

INJECTIONS OF THE COMPLEX OF SEPARATING CURVES INTO THE TORELLI COMPLEX

YOSHIKATA KIDA

ABSTRACT. We show that for all but finitely many compact orientable surfaces, any superinjective map from the complex of separating curves into the Torelli complex is induced by an element of the extended mapping class group. As an application, we prove that any injective homomorphism from a finite index subgroup of the Johnson kernel into the Torelli group for such a surface is induced by an element of the extended mapping class group.

1. INTRODUCTION

Let $S = S_{g,p}$ denote a connected, compact and orientable surface of genus g with p boundary components. Throughout the paper, we assume that a surface satisfies these conditions unless otherwise stated. Let $\chi(S) = -2g - p + 2$ denote the Euler characteristic of S . We define $\text{Mod}^*(S)$ as the *extended mapping class group* for S , i.e., the group of isotopy classes of homeomorphisms from S onto itself, where isotopy may move points of the boundary of S . The complex of curves for S , denoted by $\mathcal{C}(S)$, plays an important role in the study of various aspects of $\text{Mod}^*(S)$. In fact, a description of any automorphism of $\mathcal{C}(S)$ leads to a description of any isomorphism between finite index subgroups of $\text{Mod}^*(S)$, as discussed by Ivanov [12] and Korkmaz [17] (see also [18] for automorphisms of $\mathcal{C}(S)$). More generally, Irmak [9] introduces superinjectivity of a simplicial map from $\mathcal{C}(S)$ into itself, which is stronger than injectivity, to describe any injective homomorphism from a finite index subgroup of $\text{Mod}^*(S)$ into $\text{Mod}^*(S)$. We refer to [1], [2], [9], [10], [11] and [20] for results of this direction.

The *Johnson kernel* $\mathcal{K}(S)$ for S is defined as the subgroup of $\text{Mod}^*(S)$ generated by all Dehn twists about separating curves in S . The *Torelli group* $\mathcal{I}(S)$ for S is defined as the subgroup of $\text{Mod}^*(S)$ generated by all Dehn twists about separating curves in S and all elements of the form $t_a t_b^{-1}$ with $\{a, b\}$ a bounding pair in S , where t_c denotes the Dehn twist about a simple closed curve c in S (see Section 2 for a precise definition of these terms). These groups are normal subgroups of $\text{Mod}^*(S)$ and attract much attention in the study of mapping class groups. The complex of separating curves for S , denoted by $\mathcal{C}_s(S)$, and the Torelli complex $\mathcal{T}(S)$ for S are introduced to prove algebraic results for $\mathcal{K}(S)$ and $\mathcal{I}(S)$ similar to those for $\text{Mod}^*(S)$ mentioned above. We refer to [4], [5], [6], [14] and [16] for automorphisms of $\mathcal{C}_s(S)$ and $\mathcal{T}(S)$. In these works, for a certain surface S , any

isomorphism between finite index subgroups of $\mathcal{I}(S)$ (resp. $\mathcal{K}(S)$) is shown to be the conjugation by an element of $\text{Mod}^*(S)$.

The aim of this paper is to show that any injective homomorphism from a finite index subgroup of $\mathcal{K}(S)$ into $\mathcal{I}(S)$ is the conjugation by an element of $\text{Mod}^*(S)$. This result is obtained by describing any superinjective map from $\mathcal{C}_s(S)$ into $\mathcal{T}(S)$. We note that $\mathcal{C}_s(S)$ is a subcomplex of $\mathcal{T}(S)$ and that $\text{Mod}^*(S)$ naturally acts on $\mathcal{C}_s(S)$ and on $\mathcal{T}(S)$ (see Section 2 for a definition of these complexes). The present paper is devoted to proving the following:

Theorem 1.1. *Let $S = S_{g,p}$ be a surface with $g \geq 1$ and $|\chi(S)| \geq 4$. If $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ is a superinjective map, then the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ holds.*

Superinjective maps from $\mathcal{C}_s(S)$ into itself are fully studied in [15]. Combining a result in [15], stated in Theorem 2.2 below, we obtain the following:

Corollary 1.2. *Let S be the surface in Theorem 1.1. For any superinjective map $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$, there exists an element γ of $\text{Mod}^*(S)$ with the equality $\phi(a) = \gamma a$ for any vertex a of $\mathcal{C}_s(S)$.*

If S is a surface of genus zero, then both $\mathcal{C}_s(S)$ and $\mathcal{T}(S)$ are equal to $\mathcal{C}(S)$. The same conclusion as Corollary 1.2 is thus proved in [2]. It remains open whether the same conclusions as Theorem 1.1 and Corollary 1.2 are true for $S = S_{1,3}$. We refer to [14], [15] and [16] for known facts on the complexes $\mathcal{C}_s(S)$ and $\mathcal{T}(S)$ for a surface S with $|\chi(S)| = 3$ (see also Remark 3.1).

An idea to prove Theorem 1.1 for closed surfaces has already appeared in [4]. The proof for surfaces with non-empty boundary is much harder because of the existence of bounding pairs cutting off a pair of pants. A sketch of the proof is given in Section 3.

In the rest of this section, we state results on the groups $\mathcal{K}(S)$ and $\mathcal{I}(S)$ obtained as a consequence of Corollary 1.2.

Theorem 1.3. *Let S be the surface in Theorem 1.1. Let Γ be a finite index subgroup of $\mathcal{K}(S)$ and $f: \Gamma \rightarrow \mathcal{I}(S)$ an injective homomorphism. Then there exists a unique element γ_0 of $\text{Mod}^*(S)$ with the equality $f(\gamma) = \gamma_0 \gamma \gamma_0^{-1}$ for any $\gamma \in \Gamma$.*

This theorem is deduced by combining Proposition 6.9 in [14] with Corollary 1.2 and following the proof of Theorem 1.4 in [14].

To state consequences of Theorem 1.3, let us introduce terminology. For a group G and its subgroup Γ , the *relative commensurator* of Γ in G , denoted by $\text{Comm}_G(\Gamma)$, is defined as the subgroup of G consisting of all elements $\gamma \in G$ such that $\Gamma \cap \gamma \Gamma \gamma^{-1}$ is of finite index in both Γ and $\gamma \Gamma \gamma^{-1}$.

For a group Γ , we define $F(\Gamma)$ to be the set of isomorphisms between finite index subgroups of Γ . We say that two elements f, h of $F(\Gamma)$ are equivalent if there exists a finite index subgroup of Γ on which f and h are equal. The composition of two elements $f: \Gamma_1 \rightarrow \Gamma_2, h: \Lambda_1 \rightarrow \Lambda_2$ of $F(\Gamma)$ given by $f \circ h: h^{-1}(\Gamma_1 \cap \Lambda_2) \rightarrow f(\Lambda_2 \cap \Gamma_1)$ induces the product operation on the quotient set of $F(\Gamma)$ by this equivalence relation. This makes it into the group called the *abstract commensurator* of Γ and denoted by $\text{Comm}(\Gamma)$. If Γ is a subgroup of a group G , then we have the natural homomorphism from $\text{Comm}_G(\Gamma)$ into $\text{Comm}(\Gamma)$.

Theorem 1.4. *Let S be the surface in Theorem 1.1 and put $G = \text{Mod}^*(S)$. Let Γ be a subgroup of G with $[\mathcal{K}(S) : \Gamma \cap \mathcal{K}(S)] < \infty$ and $[\Gamma : \Gamma \cap \mathcal{I}(S)] < \infty$. Then the natural homomorphism from $\text{Comm}_G(\Gamma)$ into $\text{Comm}(\Gamma)$ is an isomorphism.*

Recall that a group Γ is said to be *co-Hopfian* if any injective homomorphism from Γ into itself is surjective.

Theorem 1.5. *Let $S = S_{g,p}$ be a surface and assume either $g \geq 3$ and $p \leq 1$ or $g = 1$ and $p \geq 4$. Then any subgroup Γ of $\text{Mod}^*(S)$ with $[\mathcal{K}(S) : \Gamma \cap \mathcal{K}(S)] < \infty$ and $[\Gamma : \Gamma \cap \mathcal{I}(S)] < \infty$ is co-Hopfian. In particular, any intermediate subgroup between $\mathcal{K}(S)$ and $\mathcal{I}(S)$ is co-Hopfian.*

The paper is organized as follows. In Section 2, we review a definition of the complexes $\mathcal{C}(S)$, $\mathcal{C}_s(S)$ and $\mathcal{T}(S)$ and the groups $\mathcal{K}(S)$ and $\mathcal{I}(S)$. We also recall known facts on simplicial maps between those complexes. In Section 3, we present an outline of the proof of Theorem 1.1. In Section 4, we introduce several simplicial graphs associated to surfaces, which will be used in subsequent sections. We provide basic properties of them. The proof of Theorem 1.1 is given throughout Sections 5–8. Details of the organization of the proof is explained in Section 3. In Section 9, we prove Theorems 1.4 and 1.5.

2. PRELIMINARIES

2.1. Terminology. Unless otherwise stated, we assume that a surface is connected, compact and orientable. Let $S = S_{g,p}$ denote a surface of genus g with p boundary components. A simple closed curve in S is said to be *essential* in S if it is neither homotopic to a point of S nor isotopic to a boundary component of S . When there is no confusion, we mean by a curve in S either an essential simple closed curve in S or the isotopy class of it. A curve a in S is said to be *separating* in S if $S \setminus a$ is not connected. Otherwise, a is said to be *non-separating* in S . These properties depend only on the isotopy class of a . A pair of non-separating curves in S , $\{a, b\}$, is called a *bounding pair (BP)* in S if a and b are disjoint and non-isotopic and if $S \setminus (a \cup b)$ is not connected. These conditions depend only on the isotopy classes of a and b . We say that two non-separating curves in S are *BP-equivalent* in S if they either are isotopic or are disjoint and form a BP in S .

A surface homeomorphic to $S_{1,1}$ is called a *handle*. A surface homeomorphic to $S_{0,3}$ is called a *pair of pants*. Let a be a separating curve in S . If a cuts off a handle from S , then a is called an *h-curve* in S . If a cuts off a pair of pants from S , then a is called a *p-curve* in S . When S is not homeomorphic to $S_{0,4}$, for a p-curve a in S and a component ∂ of ∂S , we say that a *cuts off* ∂ if the pair of pants cut off by a from S contains ∂ . A curve in S which is either an h-curve in S or a p-curve in S is called an *hp-curve* in S . If a BP b in S cuts off a pair of pants from S , then b is called a *p-BP* in S . When S is not homeomorphic to $S_{1,2}$, for a p-BP b in S and a component ∂ of ∂S , we say that b *cuts off* ∂ if the pair of pants cut off by b from S contains ∂ .

We denote by $V(S)$ the set of isotopy classes of essential simple closed curves in S . For two elements $\alpha, \beta \in V(S)$, we define $i(\alpha, \beta)$ the *geometric intersection number*, i.e., the minimal cardinality of $A \cap B$ among representatives A and B of α and β , respectively. Let $\Sigma(S)$ denote the set of non-empty finite subsets σ of $V(S)$ with $i(\alpha, \beta) = 0$ for any $\alpha, \beta \in \sigma$. We mean by a *representative* of an element σ of $\Sigma(S)$ the union of mutually disjoint representatives of elements in σ .

We extend the function i to the symmetric function on $(V(S) \sqcup \Sigma(S))^2$ so that we have $i(\alpha, \sigma) = \sum_{\beta \in \sigma} i(\alpha, \beta)$ and $i(\sigma, \tau) = \sum_{\beta \in \sigma, \gamma \in \tau} i(\beta, \gamma)$ for any $\alpha \in V(S)$ and $\sigma, \tau \in \Sigma(S)$. Let α and β be elements of $V(S) \sqcup \Sigma(S)$. We say that α and β

are *disjoint* if $i(\alpha, \beta) = 0$, and otherwise they *intersect*. For representatives A, B of α, β , respectively, we say that A and B *intersect minimally* if $|A \cap B| = i(\alpha, \beta)$.

For an element α of $V(S)$ (or its representative), we denote by S_α the surface obtained by cutting S along α . Similarly, for an element σ of $\Sigma(S)$ (or its representative), we denote by S_σ the surface obtained by cutting S along all curves in σ . Each component of S_σ is often identified with a complementary component of a tubular neighborhood of a one-dimensional submanifold representing σ in S . For each component Q of S_σ , the set $V(Q)$ is then identified with a subset of $V(S)$.

Suppose that the boundary ∂S of S is non-empty. We say that a simple arc l in S is *essential* in S if

- ∂l consists of two distinct points of ∂S ;
- l meets ∂S only at its end points; and
- l is not isotopic relative to ∂l to an arc in ∂S .

Unless otherwise stated, isotopy of essential simple arcs in S may move their end points, keeping them staying in ∂S . An essential simple arc l in S is said to be *separating* in S if $S \setminus l$ is not connected. Otherwise, l is said to be *non-separating* in S . These properties depend only on the isotopy class of l .

Let ∂_1 and ∂_2 be distinct components of ∂S . We say that an essential simple arc l in S *connects* ∂_1 and ∂_2 if one of the end point of l lies in ∂_1 and another in ∂_2 . In this case, we obtain the p-curve a in S that is the boundary component of a regular neighborhood of $l \cup \partial_1 \cup \partial_2$ in S other than ∂_1 and ∂_2 . The isotopy class of a depends only on the isotopy class of l . The curve a is then called the curve in S *defined by* l . Conversely, if b is a p-curve in S cutting off ∂_1 and ∂_2 , then up to isotopy, there exists a unique essential simple arc in S connecting ∂_1 and ∂_2 and disjoint from a curve in S isotopic to b . Such an arc is called a *defining arc* of (the isotopy class of) b .

2.2. Simplicial complexes associated to surfaces. We fix a surface S . We recall three simplicial complexes associated to S . The complex of curves is originally introduced by Harvey [8]. The complex of separating curves appears in [4], [5], [6] and [19]. The Torelli complex (with a certain marking and for a closed surface) is originally introduced by Farb-Ivanov [6].

The complex of curves. We define $\mathcal{C}(S)$ as the abstract simplicial complex such that the sets of vertices and simplices of $\mathcal{C}(S)$ are $V(S)$ and $\Sigma(S)$, respectively. The complex $\mathcal{C}(S)$ is called the *complex of curves* for S .

The complex of separating curves. Let $V_s(S)$ denote the set of all elements of $V(S)$ whose representatives are separating in S . We define $\mathcal{C}_s(S)$ as the full subcomplex of $\mathcal{C}(S)$ spanned by $V_s(S)$ and call it the *complex of separating curves* for S .

The Torelli complex. Let $V_{bp}(S)$ denote the set of all elements of $\Sigma(S)$ whose representatives are BPs in S . The *Torelli complex* for S , denoted by $\mathcal{T}(S)$, is defined as the abstract simplicial complex such that the set of vertices of $\mathcal{T}(S)$ is the disjoint union $V_s(S) \sqcup V_{bp}(S)$, and a non-empty finite subset σ of $V_s(S) \sqcup V_{bp}(S)$ is a simplex of $\mathcal{T}(S)$ if and only if any two elements of σ are disjoint. Let $V_t(S)$ denote the set of vertices of $\mathcal{T}(S)$.

For a simplex σ of $\mathcal{T}(S)$, we denote by S_σ the surface obtained by cutting S along all separating curves in σ and all non-separating curves in BPs in σ , where

isotopic curves are identified. We say that two elements b_1, b_2 of $\sigma \cap V_{bp}(S)$ are *BP-equivalent* if any two distinct curves of $b_1 \cup b_2$ form a BP in S . A *BP-equivalence class* of σ is an equivalence class of $\sigma \cap V_{bp}(S)$ with respect to the BP-equivalence relation. The following lemma is a basic observation on BPs, which will be used many times throughout the paper.

Lemma 2.1 ([14, Lemma 3.1]). *Let a be a BP in S , and let b be either a separating curve in S with $i(a, b) = 0$ or a BP in S which satisfies $i(a, b) = 0$, but is not BP-equivalent to a . Then the two curves in a are in a single component of S_b .*

Superinjective maps. Let X and Y be any of the simplicial complexes $\mathcal{C}(S)$, $\mathcal{C}_s(S)$ and $\mathcal{T}(S)$. We denote by $V(X)$ and $V(Y)$ the sets of vertices of X and Y , respectively. Note that a map $\phi: V(X) \rightarrow V(Y)$ defines a simplicial map from X into Y if and only if $i(\phi(a), \phi(b)) = 0$ for any two vertices $a, b \in V(X)$ with $i(a, b) = 0$. We mean by a *superinjective map* $\phi: X \rightarrow Y$ a simplicial map $\phi: X \rightarrow Y$ satisfying $i(\phi(a), \phi(b)) \neq 0$ for any two vertices $a, b \in V(X)$ with $i(a, b) \neq 0$. One can check that any superinjective map is injective (see Section 2.2 of [14]).

Let g denote the genus of S and p the number of boundary components of S . We assume $3g + p - 4 > 0$. As proved in [12], [17] and [18], any automorphism of $\mathcal{C}(S)$ is generally induced by an element of $\text{Mod}^*(S)$. In [1], [2], [9], [10] and [11], it is shown that any superinjective map from $\mathcal{C}(S)$ into itself is surjective. More generally, in [20], any injective simplicial map from $\mathcal{C}(S)$ into itself is shown to be surjective. As for the complex of separating curves, we know the following:

Theorem 2.2 ([15]). *Let $S = S_{g,p}$ be a surface and assume one of the following three conditions: $g \geq 3$ and $p \geq 0$; $g = 2$ and $p \geq 2$; or $g = 1$ and $p \geq 3$. Then any superinjective map from $\mathcal{C}_s(S)$ into itself is induced by an element of $\text{Mod}^*(S)$.*

It is also known that if S is the surface in Theorem 2.2, then any superinjective map from $\mathcal{T}(S)$ into itself is induced by an element of $\text{Mod}^*(S)$ (see [15]).

2.3. The Johnson kernel and the Torelli group. Let S be a surface. We define $\text{Mod}(S)$ as the *mapping class group* for S , i.e., the subgroup of $\text{Mod}^*(S)$ consisting of all isotopy classes of orientation-preserving homeomorphisms from S onto itself. We define $\text{PMod}(S)$ as the *pure mapping class group* for S , i.e., the subgroup of $\text{Mod}^*(S)$ consisting of all isotopy classes of homeomorphisms from S onto itself that preserve an orientation of S and each boundary component of S as a set. Both $\text{Mod}(S)$ and $\text{PMod}(S)$ are normal subgroups of $\text{Mod}^*(S)$ of finite index.

For each $a \in V(S)$, we denote by $t_a \in \text{PMod}(S)$ the *(left) Dehn twist* about a . The *Johnson kernel* $\mathcal{K}(S)$ is the subgroup of $\text{PMod}(S)$ generated by all t_a with $a \in V_s(S)$. The *Torelli group* $\mathcal{I}(S)$ for S is the subgroup of $\text{PMod}(S)$ generated by all t_a with $a \in V_s(S)$ and all $t_b t_c^{-1}$ with $\{b, c\} \in V_{bp}(S)$. Both $\mathcal{K}(S)$ and $\mathcal{I}(S)$ are normal subgroups of $\text{Mod}^*(S)$ because the equality $\gamma t_a \gamma^{-1} = t_{\gamma a}^\varepsilon$ holds for any $a \in V(S)$ and $\gamma \in \text{Mod}^*(S)$, where $\varepsilon = 1$ if $\gamma \in \text{Mod}(S)$, and $\varepsilon = -1$ otherwise.

3. STRATEGY

Let $S = S_{g,p}$ be a surface with $g \geq 1$ and $|\chi(S)| \geq 4$. This is equivalent to the condition that we have either $g \geq 3$ and $p \geq 0$; $g = 2$ and $p \geq 2$; or $g = 1$ and $p \geq 4$. Let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. In what follows, we present an outline to prove the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$.

Step 1. In Section 5, we prove that ϕ is χ -preserving. Namely, for each $\alpha \in V_s(S)$, if we denote by Q_1 and Q_2 the two components of S_α and denote by R_1 and R_2 the two components of $S_{\phi(\alpha)}$, then the equality $\chi(Q_j) = \chi(R_j)$ holds for each $j = 1, 2$ after exchanging the indices if necessary. In particular, ϕ sends each hp-curve in S to either an hp-curve in S or a p-BP in S .

When $p = 0$, ϕ preserves h-curves in S because there exists neither p-curve in S nor p-BP in S . The inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ then readily follows (see Section 6.1). When $p \geq 1$, the inclusion is proved by induction on p in Steps 2 and 3.

Step 2. This is the first step of the induction on p . We deal with $S_{g,1}$ with $g \geq 3$ and $S_{2,2}$ in Section 6 and deal with $S_{1,4}$ in Section 7.

When either $S = S_{g,1}$ with $g \geq 3$ or $S = S_{2,2}$, most of the proof of the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ is devoted to deducing a contradiction on the assumption that we have an h-curve a in S with $\phi(a)$ a p-BP in S . A central idea to deduce a contradiction is based on the implicit fact that there are curves in $S_{2,1}$ more than in $S_{1,3}$ in spite of the equality $\chi(S_{2,1}) = \chi(S_{1,3})$. Indeed, $S_{1,3}$ is embedded in $S_{2,1}$ as the complement of a tubular neighborhood of a non-separating curve in $S_{2,1}$. We fix a separating curve z in S such that z is disjoint from a and non-isotopic to a ; and the component of S_z containing a , denoted by X , is homeomorphic to $S_{2,1}$. We can then show that $\phi(z)$ is a BP in S containing a curve in $\phi(a)$. Since ϕ is χ -preserving, the component of $S_{\phi(z)}$, denoted by Y , containing a curve in $\phi(a)$ as an essential one is homeomorphic to $S_{1,3}$. We now pick an h-curve b in X such that $\{a, b\}$ is a sharing pair in X (see Definition 4.8). The image $\phi(b)$ is understood by using the curves in Figure 8 that are originally introduced by Brendle-Margalit [5] to characterize sharing pairs in terms of disjointness and non-disjointness. To deduce a contradiction, we introduce the simplicial graph $\mathcal{B}$ whose vertices are h-curves in X forming a sharing pair in X together with a and satisfying an additional condition. We also introduce the simplicial graph $\mathcal{G}$ whose vertices are certain p-curves in Y . Using information on $\phi(b)$, we construct an injective simplicial map from $\mathcal{B}$ into $\mathcal{G}$. On the other hand, in Section 4.5, it is shown that there exists no injective simplicial map from $\mathcal{B}$ into $\mathcal{G}$. We thus obtain a contradiction.

When $S = S_{1,4}$, on the assumption that we have an hp-curve a in S with $\phi(a)$ a p-BP in S , we deduce a contradiction in an analogous way. We aim to construct an injective simplicial map from a simplicial graph associated to $S_{1,2}$ into a simplicial graph associated to $S_{0,4}$. The definition of these graphs and that of $\mathcal{B}$ and $\mathcal{G}$ are based on a similar idea. Using results in Section 4.5, we deduce a contradiction.

Remark 3.1. When $S = S_{1,4}$, the choice of curves in Figure 14 is crucial in the construction of the injective simplicial map mentioned above. We do not know similar choice of curves in the case $S = S_{1,3}$. This is why $S_{1,3}$ is not dealt with in Theorem 1.1 although it is shown in [15] that for $S = S_{1,3}$, any superinjective map from $\mathcal{C}_s(S)$ into itself is induced by an element of $\text{Mod}^*(S)$.

Step 3. In Section 8, we deal with the remainder of surfaces. The proof consists of straightforward arguments using the hypothesis of the induction on p .

4. SIMPLICIAL GRAPHS ASSOCIATED TO SURFACES

In this section, we introduce several simplicial graphs associated to $S_{0,4}$, $S_{1,2}$, $S_{1,3}$ and $S_{2,1}$, and show results on non-existence of injective simplicial maps between those graphs. The results will be used in Section 6 and 7.

FIGURE 1.

4.1. Simplicial graphs associated to $S_{0,4}$. Throughout this subsection, we put $R = S_{0,4}$. The aim of this subsection is to provide basic facts on the graphs $\mathcal{F}$, $\mathcal{E}$ and $\mathcal{H}$ introduced below.

Graph $\mathcal{F}$. Let $R = S_{0,4}$ be a surface. We define $\mathcal{F} = \mathcal{F}(R)$ as the simplicial graph such that the set of vertices of $\mathcal{F}$ is $V(R)$, and two vertices a, b of $\mathcal{F}$ are connected by an edge of $\mathcal{F}$ if and only if we have $i(a, b) = 2$.

This graph is known to be isomorphic to the Farey graph realized as an ideal triangulation of the Poincaré disk (see Section 3.2 in [18]).

Let G be a simplicial graph. We mean by a *triangle* in G a subgraph of G consisting of exactly three vertices and exactly three edges. We say that two vertices v_1, v_2 of G lie in a *diagonal position of two adjacent triangles in G* if there exist two triangles Δ_1, Δ_2 in G such that $v_1 \in \Delta_1, v_2 \in \Delta_2$ and $\Delta_1 \cap \Delta_2$ is an edge of G containing neither v_1 nor v_2 .

Proposition 4.1. *Let $R = S_{0,4}$ be a surface and put $\mathcal{F} = \mathcal{F}(R)$. Let a and b be curves in R . Then the following three conditions are equivalent:*

- (a) *The two vertices a, b of $\mathcal{F}$ lie in a diagonal position of two adjacent triangles in $\mathcal{F}$.*
- (b) *There exist defining arcs l, r of a, b , respectively, such that the set of the two components of ∂R connected by l and that for r are equal; and l and r are disjoint and non-isotopic.*
- (c) *We have $i(a, b) = 4$.*

Proof. Let $\partial_1, \dots, \partial_4$ denote the four components of ∂R . Note that $\text{Mod}(R)$ acts transitively on the set of oriented edges of $\mathcal{F}$. It follows that $\text{PMod}(R)$ acts transitively on the set of all non-oriented edges of $\mathcal{F}$ consisting of two curves c_3, c_4 in R such that for each $j = 3, 4$, c_j cuts off a pair of pants containing ∂_1 and ∂_j from R . The group $\text{PMod}(R)$ thus acts transitively on the set of all non-ordered pairs of two curves d_1, d_2 in R such that each of d_1 and d_2 cuts off a pair of pants containing ∂_1 and ∂_2 from R ; and d_1 and d_2 lie in a diagonal position of two adjacent triangles in $\mathcal{F}$. We can thus show that condition (a) implies conditions (b) and (c) by describing four curves a_1, a_2, a_3 and a_4 in R such that each of $\{a_1, a_3, a_4\}$ and $\{a_2, a_3, a_4\}$ forms a triangle in $\mathcal{F}$.

We assume condition (b). We may assume that l and r connect ∂_1 and ∂_2 . Let $h \in \text{Mod}(R)$ be the half twist about a exchanging ∂_1 and ∂_2 and being the identity on the component of R_a containing ∂_3 and ∂_4 . If l is described as in Figure 1, then r is described as in the same Figure up to a power of h . Let s and s' be the essential simple arcs in R described in the same Figure. Let c and c' denote the curves in R

defined by s and s' , respectively. Each of $\{a, c, c'\}$ and $\{b, c, c'\}$ forms a triangle in $\mathcal{F}$. We thus obtain condition (a).

Finally, we prove that condition (c) implies condition (b). Although this can readily be shown by using Lemma 3.2 in [15], we present a direct proof without using it. We assume $i(a, b) = 4$. We may assume that a cuts off a pair of pants containing ∂_1 and ∂_2 from R . Let A and B be representatives of a and b , respectively, with $|A \cap B| = i(a, b)$. We denote by P the component of R_A containing ∂_3 and ∂_4 . We put $P' = R_A \setminus P$. Since we have $|A \cap B| = 4$, the intersection $B \cap P$ consists of two essential simple arcs in P , denoted by s_1 and s_2 . The arcs s_1 and s_2 are isotopic because P is a pair of pants. The intersection $B \cap P'$ also consists of two isotopic, essential simple arcs in P' , denoted by s_3 and s_4 .

Fix an orientation of A . For each $j = 1, 2$, we put $\partial s_j = \{p_j, q_j\}$ so that p_1, q_1, q_2 and p_2 appear along A in this order. For each $j = 3, 4$, the arc s_j connects neither p_1 and q_1 nor p_2 and q_2 because otherwise s_j and either s_1 or s_2 would form a simple closed curve in R . For each $j = 3, 4$, the arc s_j connects neither p_1 and q_2 nor p_2 and q_1 because s_j is separating in P' . It turns out that s_3 and s_4 connect either p_1 and p_2 or q_1 and q_2 .

Let I and J denote the components of $A \setminus \{p_1, p_2\}$ and $A \setminus \{q_1, q_2\}$, respectively, that contain no point of $A \cap B$. We may assume that I and ∂_1 (resp. J and ∂_2) lie in the same component of $P' \setminus B$. Pick essential simple arcs u_1, u_2 in P' such that

- u_1 connects a point of ∂_1 with a point of I , and u_2 connects a point of ∂_2 with a point of J ; and
- both u_1 and u_2 are disjoint from $B \cap P'$.

Since $s_1 \cup s_2$ cuts off from P a disk whose boundary is the union of s_1, s_2, I and J , there exists an essential simple arc u_3 in P disjoint from $B \cap P$ and connecting the point of $u_1 \cap I$ with the point of $u_2 \cap J$. We define r as the union $u_1 \cup u_2 \cup u_3$, which is an essential simple arc in R connecting ∂_1 and ∂_2 and disjoint from B . Pick an essential simple arc l in P' connecting ∂_1 and ∂_2 and disjoint from u_1 and u_2 . The arc l is disjoint from A and r . Condition (b) is obtained. $\square$

Lemma 7.2 motivates us to introduce the following:

Graph $\mathcal{E}$. Let $R = S_{0,4}$ be a surface. Fix two distinct components ∂_1, ∂_2 of ∂R . We define a simplicial graph $\mathcal{E} = \mathcal{E}(R; \partial_1, \partial_2)$ as follows: Vertices of $\mathcal{E}$ are elements a of $V(R)$ such that ∂_1 and ∂_2 are contained in the same component of R_a . Two vertices a, b of $\mathcal{E}$ are connected by an edge of $\mathcal{E}$ if and only if we have $i(a, b) = 4$.

Proposition 4.2. *In the above notation, the graph $\mathcal{E}$ is a tree.*

Proof. Let $V(\mathcal{E})$ denote the set of vertices of $\mathcal{E}$. Let $\mathcal{F}$ denote the graph $\mathcal{F}(R)$. By Proposition 4.1, for any two vertices a, b of $\mathcal{E}$, a and b form an edge of $\mathcal{E}$ if and only if a and b lie in a diagonal position of two adjacent triangles in $\mathcal{F}$. A notable property of the graph $\mathcal{F}$ is that for each edge e of $\mathcal{F}$, the set $\mathcal{F} \setminus \bar{e}$ has exactly two connected components, where $\bar{e}$ denotes the closure $e \cup \partial e$ of e in the geometric realization of $\mathcal{F}$. Let us call a component of $\mathcal{F} \setminus \bar{e}$ a *side* of e . For each vertex v of $\mathcal{F}$ and each edge e of $\mathcal{F}$ with $v \notin \partial e$, we denote by $X_{v,e}$ the set of all vertices of $\mathcal{F}$ contained in the side of e that does not contain v . For each vertex v of $\mathcal{F}$, let E_v denote the set of all edges e of $\mathcal{F}$ such that v and e are contained in a single triangle in $\mathcal{F}$ with $v \notin \partial e$. If $v \in V(\mathcal{E})$, then $V(\mathcal{E}) \setminus \{v\}$ is equal to the disjoint union $\bigsqcup_{e \in E_v} (X_{v,e} \cap V(\mathcal{E}))$.

FIGURE 2. (a) The Farey graph; (b) The link of a in $\mathcal{H}$

Fix $v_0 \in V(\mathcal{E})$. We construct a deformation retraction of $\mathcal{E}$ into v_0 . We define a map $f: V(\mathcal{E}) \rightarrow V(\mathcal{E})$ as follows. Set $f(v_0) = v_0$. For each $v \in V(\mathcal{E})$ with $v \neq v_0$, choose a unique edge e of E_v with $v_0 \in X_{v,e}$. Let Δ be the triangle in $\mathcal{F}$ that contains e , but does not contain v . We define $f(v) \in V(\mathcal{E})$ as the vertex of Δ that is not a vertex of e .

By the definition of f , for each $v \in V(\mathcal{E})$, $f(v)$ and v either are equal or form an edge of $\mathcal{E}$. We claim that for each edge $\{u, v\}$ of $\mathcal{E}$, either $f(u) = v$ or $f(v) = u$ holds. In particular, f defines a simplicial map from $\mathcal{E}$ into itself. If either u or v is v_0 , then $f(u) = f(v) = v_0$. Assume that neither u nor v is v_0 . Let e be the edge of $\mathcal{F}$ such that u and v lie in distinct sides of e . Note that v_0 is not a vertex of e because no vertex of e corresponds to a curve in R cutting off a pair of pants containing ∂_1 and ∂_2 from R . If v_0 and v are in the same side of e , then $f(u) = v$. If v_0 and u are in the same side of e , then $f(v) = u$. The claim follows.

If v is a vertex of $\mathcal{E}$ with $v \neq v_0$, then with respect to the path metric on $\mathcal{F}$, the distance between v_0 and $f(v)$ is strictly smaller than that between v_0 and v by the definition of f . For each $v \in V(\mathcal{E})$, there thus exists a positive integer n with $f^n(v) = v_0$. The iteration of f defines a deformation retraction of $\mathcal{E}$ into v_0 . $\square$

Lemma 7.4 motivates us to introduce the following:

Graph $\mathcal{H}$. Let $R = S_{0,4}$ be a surface and put $\mathcal{F} = \mathcal{F}(R)$. We fix two distinct components ∂_1, ∂_2 of ∂R . We define the simplicial graph $\mathcal{H} = \mathcal{H}(R; \partial_1, \partial_2)$ as follows: Vertices of $\mathcal{H}$ are elements a of $V(R)$ such that ∂_1 and ∂_2 lie in distinct components of R_a . Two vertices a, b of $\mathcal{H}$ are connected by an edge of $\mathcal{H}$ if and only if either we have $i(a, b) = 2$ or a and b lie in a diagonal position of two adjacent triangles in $\mathcal{F}$.

Lemma 4.3. *In the above notation, for each vertex a of $\mathcal{H}$, the link of a in $\mathcal{H}$ is the graph described in Figure 2 (b), where the vertices b_n and c_n are located so that for each $n \in \mathbb{Z}$,*

- we have $i(a, b_n) = i(b_n, c_{2n}) = i(b_n, c_{2n+1}) = 2$;
- a and c_n lie in a diagonal position of two adjacent triangles in $\mathcal{F}$; and

FIGURE 3. The three curves a , b and c form a triangle in $\mathcal{D}$.

- b_n and b_{n+1} lie in a diagonal position of two adjacent triangles in $\mathcal{F}$.

Proof. We first note that if a_1 , a_2 and a_3 are vertices of $\mathcal{F}$ forming a triangle in $\mathcal{F}$, then exactly two of them are vertices of $\mathcal{H}$. Let L denote the link of a in $\mathcal{H}$. Let P denote the component of R_a containing ∂_1 as its boundary component. We define $h \in \text{Mod}(R)$ as the half twist about a exchanging the two components of ∂R contained in P and being the identity on $R_a \setminus P$. If we pick a vertex b_0 of $\mathcal{H}$ with $i(a, b_0) = 2$, then the set $\{h^n(b_0)\}_{n \in \mathbb{Z}}$ is equal to the set of all vertices b of $\mathcal{F}$ with $i(a, b) = 2$. We set $b_n = h^{2n}(b_0)$ for each $n \in \mathbb{Z}$ and set $B = \{b_n\}_{n \in \mathbb{Z}}$. It follows that B is equal to the set of all vertices b in L with $i(a, b) = 2$.

We define C as the set of all vertices c of $\mathcal{F}$ such that a and c lie in a diagonal position of two adjacent triangles in $\mathcal{F}$. Any element of C is a vertex of $\mathcal{H}$ and thus of L , and any two elements of C are sent to each other by a power of h . There exists a unique element c_0 of C with $i(b_0, c_0) = i(b_0, h(c_0)) = 2$. We set $c_n = h^n(c_0)$ for each $n \in \mathbb{Z}$. The vertices b_n and c_m are located as in Figure 2 (a) and satisfy desired conditions. $\square$

4.2. A simplicial graph associated to $S_{1,2}$. Throughout this subsection, we put $Q = S_{1,2}$. The following simplicial graph associated to Q is studied in [15].

Graph $\mathcal{D}$. Let $Q = S_{1,2}$ be a surface. We define $\mathcal{D} = \mathcal{D}(Q)$ as the simplicial graph such that the set of vertices of $\mathcal{D}$ is $V_s(Q)$, and two vertices a, b of $\mathcal{D}$ are connected by an edge of $\mathcal{D}$ if and only if we have $i(a, b) = 4$.

We note that $\text{PMod}(Q)$ acts transitively on the set of edges of $\mathcal{D}$ (see the paragraph right after the proof of Lemma 3.2 in [15]). It follows that for any edge $\{a, b\}$ of $\mathcal{D}$, there exists a unique element of $V(Q)$ disjoint from a and b . We denote it by $c(a, b)$. The curve $c(a, b)$ is non-separating in Q (see Figure 3).

For each vertex a of $\mathcal{D}$, we denote by $\text{Lk}_{\mathcal{D}}(a)$ the link of a in $\mathcal{D}$, and denote by $V(\text{Lk}_{\mathcal{D}}(a))$ the set of vertices of $\text{Lk}_{\mathcal{D}}(a)$. We mean by a *bi-infinite line* a simplicial graph consisting of vertices v_j indexed by each integer j such that for any $j, k \in \mathbb{Z}$, v_j and v_k are adjacent if and only if $k = j - 1$ or $j + 1$. Basic properties of the link of each vertex in $\mathcal{D}$ are summarized as follows.

Proposition 4.4 ([15, Lemma 3.4]). *In the notation in the definition of the graph $\mathcal{D}$, we fix a vertex a of $\mathcal{D}$. Let H denote the handle cut off by a from Q . We define $h \in \text{Mod}(Q)$ as the half twist about a exchanging the two components of ∂Q and being the identity on H . Pick two elements u, v of $V(H)$ with $i(u, v) = 1$. We put*

$$W = \{w \in V(\text{Lk}_{\mathcal{D}}(a)) \mid c(a, w) = u\}, \quad Z = \{z \in V(\text{Lk}_{\mathcal{D}}(a)) \mid c(a, z) = v\}.$$

Then after an appropriate numbering, we have the equalities $W = \{w_n\}_{n \in \mathbb{Z}}$, $Z = \{z_m\}_{m \in \mathbb{Z}}$ and

$$h(w_n) = w_{n+1}, \quad h(z_m) = z_{m+1} \quad \text{for any } n, m \in \mathbb{Z},$$

and the full subgraph of $\mathcal{D}$ spanned by all vertices of $W \cup Z$ is the bi-infinite line such that for each $n \in \mathbb{Z}$, w_n is adjacent to z_n and z_{n+1} .

4.3. A simplicial graph associated to $S_{1,3}$. We define the simplicial graph $\mathcal{G}$ associated to $S_{1,3}$ and show that $\mathcal{G}$ is a bi-infinite line. To define the graph $\mathcal{G}$, we introduce sharing pairs of p-curves, motivated by sharing pairs of h-curves originally introduced by Brendle-Margalit [4] (see Definition 4.8).

Definition 4.5. Let $S = S_{g,p}$ be a surface with $g \geq 1$ and $p \geq 2$. Pick two distinct components ∂_1, ∂_2 of ∂S . Let a and b be p-curves in S cutting off ∂_1 and ∂_2 . Let l and r be defining arcs of a and b , respectively, connecting ∂_1 and ∂_2 . We call the pair $\{a, b\}$ a *sharing pair* in S if l and r can be chosen so that they are disjoint and non-isotopic; and the surface obtained by cutting S along $l \cup r$ is connected.

If l and r are arcs in S satisfying the conditions in Definition 4.5, then r is an essential simple arc in the surface obtained by cutting S along l . Moreover, r is non-separating in that surface. Since a and b are defined by l and r , respectively, the group $\text{PMod}(S)$ acts transitively on the set of sharing pairs in S of p-curves cutting off ∂_1 and ∂_2 .

Let $Q = S_{1,2}$ be a surface. Pick a component ∂ of Q . We define $\mathcal{A} = \mathcal{A}(Q, \partial)$ as the set of ordered pairs (r, r') of essential simple arcs in Q such that

- each of r and r' connects two points of ∂ and is non-separating in Q ;
- r and r' are disjoint and non-isotopic; and
- the end points of r and r' appear alternately along ∂ .

Remark 4.6. Let (r, r') be an element of $\mathcal{A}$. We denote by P the surface obtained by cutting Q along r , which is a pair of pants. The component ∂ of ∂Q is then decomposed into two arcs s_1, s_2 , which are contained in distinct components of ∂P . Since the end points of r and r' appear alternately along ∂ , r' is an essential simple arc in P connecting a point of s_1 with a point of s_2 . Such an essential simple arc in P uniquely exists up to a homeomorphism of Q fixing r as a set. It turns out that the group of homeomorphisms of Q fixing ∂ as a set acts on $\mathcal{A}$ transitively.

Let $Y = S_{1,3}$ be a surface. Fix a p-curve a in Y . We denote by Q the component of Y_a homeomorphic to $S_{1,2}$, and denote by ∂ the component of ∂Y contained in Q . For each essential simple arc s in Q which connects two points of ∂ and is non-separating in Q , we define $\Gamma(s) = \Gamma(a; s)$ as the set of all elements γ of $V(Y)$ such that γ is a p-curve in Y cutting off the two components of ∂Y distinct from ∂ ; a and γ form a sharing pair in Y ; and a representative of γ is disjoint from s .

Graph $\mathcal{G}$. Let $Y = S_{1,3}$ be a surface. We fix a p-curve a in Y and define Q and ∂ as above. For each element (r, r') of $\mathcal{A}(Q, \partial)$, we define $\mathcal{G} = \mathcal{G}(Y, a; r, r')$ as the simplicial graph such that the set of vertices of $\mathcal{G}$ is the union $\Gamma(r) \cup \Gamma(r')$, and two vertices γ, γ' of $\mathcal{G}$ are connected by an edge of $\mathcal{G}$ if and only if γ and γ' form a sharing pair in Y .

Proposition 4.7. *In the notation in the definition of the graph $\mathcal{G}$, we define $h \in \text{Mod}(Y)$ as the half twist about a exchanging the two components of ∂Y contained in*

FIGURE 4.

$Y_a \setminus Q$ and being the identity on Q . Let (r, r') be an element of $\mathcal{A}(Q, \partial)$. Then after an appropriate numbering, we have the equalities $\Gamma(r) = \{\gamma_n\}_{n \in \mathbb{Z}}$, $\Gamma(r') = \{\gamma'_m\}_{m \in \mathbb{Z}}$ and

$$h(\gamma_n) = \gamma_{n+1}, \quad h(\gamma'_m) = \gamma'_{m+1} \quad \text{for any } n, m \in \mathbb{Z},$$

and the graph $\mathcal{G}$ is the bi-infinite line such that for each $n \in \mathbb{Z}$, γ_n is adjacent to γ'_n and γ'_{n+1} .

Proof. The proof is similar to that of Proposition 4.4. Put $\Gamma = \Gamma(r)$ and $\Gamma' = \Gamma(r')$. Let R denote the surface obtained by cutting Y along r . The set Γ is then a subset of $V(R)$. Let $\mathcal{F}(R)$ denote the graph introduced in Section 4.1. By Proposition 4.1, for each element γ of Γ , a and γ lie in a diagonal position of two adjacent triangles in $\mathcal{F}(R)$. Since the cyclic group generated by h acts transitively on the set of triangles in $\mathcal{F}(R)$ containing a , it also acts transitively on Γ . We thus have the equality $\Gamma = \{h^n(\gamma_0)\}_{n \in \mathbb{Z}}$ for some $\gamma_0 \in \Gamma$. We put $\gamma_n = h^n(\gamma_0)$ for each $n \in \mathbb{Z}$. By the criterion on geometric intersection numbers in Exposé 3, Proposition 10 in [7], we have $i(\gamma_0, \gamma_n) = 8|n|$ for any $n \in \mathbb{Z}$. Since we have $i(u, v) = 4$ for any two adjacent vertices u, v of $\mathcal{G}$, any two distinct elements of Γ are not adjacent in $\mathcal{G}$.

By Remark 4.6, r and r' are described as in Figure 4. We can find two elements $\gamma'_0, \gamma'_1 = h(\gamma'_0)$ of Γ' adjacent to γ_0 in $\mathcal{G}$ as in the same Figure. Applying the argument in the last paragraph to Γ' and r' in place of Γ and r , respectively, we obtain the equality $\Gamma' = \{\gamma'_n\}_{n \in \mathbb{Z}}$, where we put $\gamma'_n = h^n(\gamma'_0)$ for each $n \in \mathbb{Z}$. Moreover, any two distinct elements of Γ' are not adjacent in $\mathcal{G}$. By the criterion in [7] applied in the last paragraph, we have $i(\gamma_0, \gamma'_n) = 4|2n - 1|$ for any $n \in \mathbb{Z}$. Since for each $n \in \mathbb{Z}$, $h^n(\gamma_0)$ is adjacent to $h^n(\gamma'_0)$ and $h^n(\gamma'_1)$ in $\mathcal{G}$, the latter assertion in the lemma follows. $\square$

4.4. A simplicial graph associated to $S_{2,1}$. The simplicial graph $\mathcal{B}$ introduced in this subsection is analogous to the graphs $\mathcal{D}$ and $\mathcal{G}$. For an h-curve A in a surface S with $|\chi(S)| \geq 3$, we denote by H_A the handle cut off by A from S , which is naturally identified with a subsurface of S .

Definition 4.8. Let $S = S_{g,p}$ be a surface with $g \geq 2$ and $|\chi(S)| \geq 3$. Let $\alpha, \beta \in V_s(S)$ be h-curves in S and $c \in V(S)$ a non-separating curve in S . We say that α and β *share* c if there exist representatives A, B and C of α, β and c , respectively, such that we have $|A \cap B| = i(\alpha, \beta)$, $H_A \cap H_B$ is an annulus with its core curve C , and $S \setminus (H_A \cup H_B)$ is connected. In this case, $\{\alpha, \beta\}$ is called a *sharing pair* for c or a *sharing pair* in S if c is not specified.

Sharing pairs are introduced by Brendle-Margalit [4]. Let c be a non-separating curve in S . Let α and β be h-curves in S disjoint from c and cutting off a handle containing c from S . The two curves α and β share c if and only if α and β form a sharing pair in S_c in the sense of Definition 4.5. It follows that $\text{PMod}(S)$ acts transitively on the set of sharing pairs in S .

We put $X = S_{2,1}$. Let a be an h-curve in S . We denote by Q the component of X_a homeomorphic to $S_{1,2}$, and put $\partial = \partial X$. For each essential simple arc s in Q which connects two points of ∂ and is non-separating in Q , we define $B(s) = B(a; s)$ as the set of all elements β of $V(X)$ such that β is an h-curve in X ; a and β form a sharing pair in X ; and a representative of β is disjoint from s .

Graph $\mathcal{B}$. Let $X = S_{2,1}$ be a surface. We fix an h-curve a in X and define Q and ∂ as above. For each element (r, r') of $\mathcal{A}(Q, \partial)$, we define $\mathcal{B} = \mathcal{B}(X, a; r, r')$ as the simplicial graph such that the set of vertices of $\mathcal{B}$ is the union $B(r) \cup B(r')$, and two vertices β, β' of $\mathcal{B}$ are connected by an edge of $\mathcal{B}$ if and only if β and β' form a sharing pair in X .

Lemma 4.9. *In the notation of the definition of the graph $\mathcal{B}$, there exists a proper subset V of the union $B(r) \cup B(r')$ such that the full subgraph of $\mathcal{B}$ spanned by V is a bi-infinite line.*

Proof. Let c be a curve in the handle cut off by a from X . We denote by Y the surface obtained by cutting X along c . We define V as the set of vertices of the graph $\mathcal{G} = \mathcal{G}(Y, a; r, r')$. The set V is identified with a subset of $B(r) \cup B(r')$, and $\mathcal{G}$ is then the full subgraph of $\mathcal{B}$ spanned by V . Proposition 4.7 shows that $\mathcal{G}$ is a bi-infinite line. The set V is proper in $B(r) \cup B(r')$ because there exists an element b of $B(r)$ such that $\{a, b\}$ is a sharing pair for a curve in X distinct from c . $\square$

4.5. Non-existence of injections. We show results on non-existence of injective simplicial maps between graphs introduced in prior subsections. We note that the isomorphism classes of the graphs $\mathcal{E}(R; \partial_1, \partial_2)$, $\mathcal{H}(R; \partial_1, \partial_2)$, $\mathcal{D}(Q)$, $\mathcal{G}(Y, a; r, r')$ and $\mathcal{B}(X, a; r, r')$ do not depend on the choice of objects inside the brackets. We thus omit those symbols in the argument of this subsection.

Lemma 4.10. *There exists no injective simplicial map from $\mathcal{D}$ into $\mathcal{E}$.*

Proof. As described in Figure 3, there exists a triangle in $\mathcal{D}$. Since $\mathcal{E}$ is a tree by Proposition 4.2, the lemma follows. $\square$

It is a plain fact that any injective simplicial map from a bi-infinite line into a bi-infinite line is surjective. This property is crucial in the proof of the following two lemmas.

Lemma 4.11. *There exists no injective simplicial map from $\mathcal{D}$ into $\mathcal{H}$.*

Proof. Let a be a vertex of $\mathcal{D}$. There exist pairwise distinct, infinitely many bi-infinite lines in the link of a in $\mathcal{D}$. For in Proposition 4.4, if the two elements u, v are varied, then we obtain distinct bi-infinite lines in the link of a in $\mathcal{D}$. On the other hand, Figure 2 (b) shows that for each vertex a' of $\mathcal{H}$, there exists exactly one bi-infinite line in the link of a' in $\mathcal{H}$. We therefore obtain the lemma. $\square$

Proposition 4.7 and Lemma 4.9 imply the following:

Lemma 4.12. *There exists no injective simplicial map from $\mathcal{B}$ into $\mathcal{G}$.*

5. PRESERVATION OF THE EULER CHARACTERISTIC

Let $S = S_{g,p}$ be a surface. A simplex σ of $\mathcal{T}(S)$ is said to be *weakly rooted* if for each BP b in σ , there exists a curve $\beta \in b$ contained in any BP in σ that is BP-equivalent to b . A simplex σ of $\mathcal{T}(S)$ is said to be *rooted* if σ consists of BPs and there is a non-separating curve β in S contained in any BP of σ . In this case, if $|\sigma| \geq 2$, then β is uniquely determined and is called the *root curve* for σ .

We note that the maximal number of vertices in a simplex of $\mathcal{C}_s(S)$ is equal to $|\chi(S)| - 1 = 2g + p - 3$ by Lemma 3.3 in [14].

Lemma 5.1. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 3$. Then the following assertions hold:*

- (i) *Any weakly rooted simplex of $\mathcal{T}(S)$ consists of at most $2g + p - 3$ vertices.*
- (ii) *Let σ be a simplex of $\mathcal{T}(S)$ with $|\sigma| = 2g + p - 3$. Suppose that for each $a \in \sigma$, we have a vertex b of $\mathcal{T}(S)$ with $i(a, b) \neq 0$ and $i(c, b) = 0$ for any $c \in \sigma \setminus \{a\}$. Then σ is weakly rooted, and each component of S_σ is either a handle or a pair of pants.*

Proof. Let σ be a simplex of $\mathcal{T}(S)$. We put

$$\sigma = \{\alpha_1, \dots, \alpha_s, b_{11}, \dots, b_{1u_1}, b_{21}, \dots, b_{t1}, \dots, b_{tu_t}\},$$

where each α_j is a separating curve in S and each b_{kl} is a BP in S such that for each $k = 1, \dots, t$, the family $\{b_{k1}, \dots, b_{ku_k}\}$ is a BP-equivalence class in σ .

We first suppose that σ is weakly rooted. For each k , there then exists a curve β_{k0} in S with $\beta_{k0} \in b_{kl}$ for any l . Let Q be the surface obtained by cutting S along all the curves $\beta_{10}, \beta_{20}, \dots, \beta_{t0}$. For each $k = 1, \dots, t$ and each $l = 1, \dots, u_k$, let β_{kl} denote the curve in b_{kl} distinct from β_{k0} . The family

$$\tau = \{\alpha_1, \dots, \alpha_s, \beta_{11}, \dots, \beta_{1u_1}, \beta_{21}, \dots, \beta_{t1}, \dots, \beta_{tu_t}\}$$

is a simplex of $\mathcal{C}_s(Q)$. Since any simplex of $\mathcal{C}_s(Q)$ consists of at most $2g + p - 3$ vertices, we have $|\sigma| = |\tau| \leq 2g + p - 3$. Assertion (i) is proved.

We next suppose that σ is a simplex of $\mathcal{T}(S)$ satisfying $|\sigma| = 2g + p - 3$ and the assumption in assertion (ii). For any k, l , we then have a curve γ_{kl} in b_{kl} , but not in $b_{kl'}$ for any $l' \in \{1, \dots, u_k\} \setminus \{l\}$. For each k , we denote by γ_{k0} the curve in b_{k1} distinct from γ_{k1} . Let R be the surface obtained by cutting S along all the curves $\gamma_{10}, \gamma_{20}, \dots, \gamma_{t0}$. The family

$$\rho = \{\alpha_1, \dots, \alpha_s, \gamma_{11}, \dots, \gamma_{1u_1}, \gamma_{21}, \dots, \gamma_{t1}, \dots, \gamma_{tu_t}\}$$

is a simplex of $\mathcal{C}_s(R)$. The assumption $|\sigma| = 2g + p - 3$ implies that ρ is a simplex of $\mathcal{C}_s(R)$ of maximal dimension. It follows that for any k, l , the BP b_{kl} consists of two of $\gamma_{k0}, \gamma_{k1}, \dots, \gamma_{ku_k}$. Since b_{kl} does not contain $\gamma_{kl'}$ for any $l' \in \{1, \dots, u_k\} \setminus \{l\}$, we have $b_{kl} = \{\gamma_{k0}, \gamma_{kl}\}$. It turns out that σ is weakly rooted. Since each component of R_ρ is either a handle or a pair of pants by Lemma 3.3 in [14], so is each component of S_σ . Assertion (ii) is proved. $\square$

Lemma 5.2. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 3$, and let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. Then ϕ sends each simplex of $\mathcal{C}_s(S)$ to a weakly rooted simplex of $\mathcal{T}(S)$.*

Moreover, the following assertion holds: Let σ be a simplex of $\mathcal{C}_s(S)$ and α an element of σ . Let R_1 and R_2 denote the two components of $S_{\phi(\alpha)}$. Then for each

$\beta \in \sigma$, it is impossible that $\phi(\beta)$ is a BP in S with one curve of $\phi(\beta)$ essential in R_1 and another essential in R_2 .

Proof. Let σ be a simplex of $\mathcal{C}_s(S)$. We choose a simplex τ of $\mathcal{C}_s(S)$ of maximal dimension containing σ . Since $\phi(\tau)$ satisfies the assumption in Lemma 5.1 (ii), $\phi(\tau)$ is weakly rooted. It follows that $\phi(\sigma)$ is also weakly rooted. The latter assertion of the lemma follows from the former assertion and Lemma 2.1. $\square$

Lemma 5.3. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 3$, and let σ be a weakly rooted simplex of $\mathcal{T}(S)$ with $|\sigma| = 2g + p - 3$. Then the number of vertices in σ corresponding to either an hp-curve in S or a p-BP in S is at most $g + \lfloor p/2 \rfloor$.*

Proof. We prove the lemma by induction on the number of BP-equivalence classes in σ . When there is no BP in σ , the lemma is obvious. Otherwise, we pick a BP-equivalence class $\{b_1, \dots, b_n\}$ in σ and write $b_j = \{\beta_0, \beta_j\}$ for each j with β_0 the root curve. We put $R = S_{\beta_0}$. Let τ be the simplex of $\mathcal{T}(R)$ induced by σ , that is, the simplex consisting of $\beta_1, \dots, \beta_n$ and all elements in $\sigma \cap V_s(S)$ and in $(\sigma \setminus \{b_1, \dots, b_n\}) \cap V_{bp}(S)$. The hypothesis of the induction shows the number of vertices in τ corresponding to either an hp-curve in R or a p-BP in R is at most $(g-1) + \lfloor (p+2)/2 \rfloor = g + \lfloor p/2 \rfloor$. Let α be an h-curve in σ . Since α is disjoint from the BP $\{\beta_0, \beta_1\}$, the handle cut off by α from S does not contain β_0 . It follows that α is an h-curve in R . Each p-curve in σ is a p-curve in R . Let b be a p-BP in σ . If b is equal to b_j for some $j = 1, \dots, n$, then β_j is a p-curve in R . Otherwise, b is a p-BP in R . The lemma thus follows. $\square$

To prove the next lemma, let us recall reduction system graphs introduced in [21]. The *reduction system graph* $G(\tau)$ for a simplex τ of $\mathcal{C}(S)$ is defined as follows. Vertices of $G(\tau)$ are components of S_τ . Edges of $G(\tau)$ are curves in τ . The two ends of the edge corresponding to a curve c in τ are defined to be vertices corresponding to components of S_τ which lie in the left and right hand sides of c in S . Note that $G(\tau)$ may have a loop. We refer to [21] for basics of reduction system graphs.

Lemma 5.4. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 3$, and let σ be a weakly rooted simplex of $\mathcal{T}(S)$ with $|\sigma| = 2g + p - 3$. Choose a component P of S_σ such that P is a pair of pants and each component of ∂P corresponds to a curve of σ . Then at least one of the three curves corresponding to components of ∂P is separating in S .*

Proof. Let δ_1, δ_2 and δ_3 denote the elements of σ corresponding to components of ∂P . We claim that these three elements are mutually distinct as elements of $V(S)$. For otherwise two of them, say δ_2 and δ_3 , would be equal and be non-separating in S . The curve δ_1 then cuts off a handle from S , in which $\delta_2 = \delta_3$ is contained. We obtain a contradiction because any non-separating curve in S forming a BP in S with δ_2 intersects δ_1 .

Assuming that any of δ_1, δ_2 and δ_3 is a non-separating curve in S , we deduce a contradiction. If two of δ_1, δ_2 and δ_3 were BP-equivalent, then another curve would be separating in S . It follows that any two of δ_1, δ_2 and δ_3 are not BP-equivalent. We put

$$\sigma = \{\alpha_1, \dots, \alpha_s, b_{11}, \dots, b_{1u_1}, b_{21}, \dots, b_{t1}, \dots, b_{tu_t}\},$$

where each α_j is a separating curve in S and each b_{kl} is a BP in S such that for each $k = 1, \dots, t$, the family $\{b_{k1}, \dots, b_{ku_k}\}$ is a BP-equivalence class in σ . Let us

define the simplex τ of $\mathcal{C}(S)$ by

$$\tau = \{\alpha_1, \dots, \alpha_s\} \cup \bigcup_{k=1}^t \{\beta_{k0}, \beta_{k1}, \dots, \beta_{ku_k}\},$$

where we put $b_{kl} = \{\beta_{k0}, \beta_{kl}\}$ with β_{k0} the root curve. Without loss of generality, we may assume that for each $k = 1, 2, 3$, δ_k is equal to β_{kl} for some l . Since the union of δ_1 , δ_2 and δ_3 cuts off P from S , for any l_1 , l_2 and l_3 , the union of β_{1l_1} , β_{2l_2} and β_{3l_3} also decomposes S into at least two components. It follows that for any maximal tree T in the reduction system graph $G(\tau)$, there exists $r \in \{1, 2, 3\}$ such that all edges corresponding to $\beta_{r0}, \beta_{r1}, \dots, \beta_{ru_r}$ are contained in T . Without loss of generality, we may assume $r = 1$. Since the number of edges of T is equal to $|\chi(S)| - 1 = 2g + p - 3$, we have

$$2g + p - 3 \geq s + (u_1 + 1) + \sum_{k=2}^t u_k > s + \sum_{k=1}^t u_k = |\sigma|.$$

This is a contradiction. $\square$

Let S be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. To state explicitly the property that ϕ is χ -preserving, let us introduce terminology. Fix $\alpha \in V_s(S)$. Let β be an element of $V_s(S)$ disjoint and distinct from α . If $\phi(\alpha) \in V_s(S)$, then there exists a unique component R of $S_{\phi(\alpha)}$ with $\phi(\beta) \in V_t(R)$ by Lemma 2.1. If $\phi(\alpha) \in V_{bp}(S)$, then there exists a unique component R of $S_{\phi(\alpha)}$ such that either

- we have $\phi(\beta) \in V_s(R)$;
- we have $\phi(\beta) \in V_{bp}(R)$, and the two components of ∂R corresponding to curves of $\phi(\alpha)$ are contained in a single component of $R_{\phi(\beta)}$; or
- we have $\phi(\beta) \in V_{bp}(S)$, and $\phi(\beta)$ consists of an element of $\phi(\alpha)$ and an element of $V_s(R)$

by Lemmas 2.1 and 5.2. Let us denote this component R by $R(\phi, \alpha; \beta)$.

For each $\beta \in V_s(S)$ disjoint and distinct from α , putting $R = R(\phi, \alpha; \beta)$, we define an element $\phi_\alpha(\beta)$ of $V_t(R)$ as follows:

- If $\phi(\beta) \in V_t(R)$, then we set $\phi_\alpha(\beta) = \phi(\beta)$.
- Otherwise $\phi(\alpha)$ and $\phi(\beta)$ are BPs in S sharing a curve. We define $\phi_\alpha(\beta)$ as another curve in $\phi(\beta)$, which is essential and separating in R .

Lemma 5.5. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 3$, and let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. Fix $\alpha \in V_s(S)$. Let Q be a component of S_α with $|\chi(Q)| \geq 2$. Then there exists a component R of $S_{\phi(\alpha)}$ such that for any $\beta \in V_s(Q)$, the equality $R = R(\phi, \alpha; \beta)$ holds.*

Proof. It is enough to show that for any $\beta_1, \beta_2 \in V_s(Q)$, the equality $R(\phi, \alpha; \beta_1) = R(\phi, \alpha; \beta_2)$ holds. We put $R_j = R(\phi, \alpha; \beta_j)$ for each $j = 1, 2$. Choose $\gamma \in V_s(Q)$ intersecting both β_1 and β_2 . Superinjectivity of ϕ implies that $\phi(\gamma)$ intersects both $\phi(\beta_1)$ and $\phi(\beta_2)$. We put $R = R(\phi, \alpha; \gamma)$. If R_1 and R_2 were distinct, then we would have $k \in \{1, 2\}$ with $R_k \neq R$. Since $\phi_\alpha(\beta_k)$ and $\phi_\alpha(\gamma)$ are then disjoint, $\phi(\beta_k)$ and $\phi(\gamma)$ are also disjoint. This is a contradiction. $\square$

In the notation in Lemma 5.5, we denote the component R by $\phi_\alpha(Q)$. Pick a separating curve α in S . We first assume that α is an hp-curve in S . Let us say that ϕ is χ -preserving at α if $\phi(\alpha)$ is either an hp-curve in S or a p-BP in S . We next

assume that α is not an hp-curve in S . Let Q_1 and Q_2 denote the two components of S_α , which satisfy $|\chi(Q_1)| \geq 2$ and $|\chi(Q_2)| \geq 2$. We say that ϕ is χ -preserving at α if we have $\phi_\alpha(Q_1) \neq \phi_\alpha(Q_2)$ and $\chi(\phi_\alpha(Q_j)) = \chi(Q_j)$ for each $j = 1, 2$. If ϕ is χ -preserving at γ for any $\gamma \in V_s(S)$, then ϕ is said to be χ -preserving. To prove that ϕ is χ -preserving, we need the following:

Lemma 5.6. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 4$, and let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. Let α be a separating curve in S which is not an hp-curve in S . If $\phi(\alpha)$ is neither an hp-curve in S nor a p-BP in S , then ϕ is χ -preserving at α .*

Proof. Let Q_1 and Q_2 denote the two components of S_α . For each $j = 1, 2$, we put $R_j = \phi_\alpha(Q_j)$. We note that for each $j = 1, 2$ and each simplex σ of $\mathcal{C}_s(Q_j)$, the family $\{\phi_\alpha(\beta) \mid \beta \in \sigma\}$ is a weakly rooted simplex of $\mathcal{T}(R_j)$ with its cardinality $|\sigma|$. Since for a surface X , any weakly rooted simplex of $\mathcal{T}(X)$ consists of at most $|\chi(X)| - 1$ vertices, we have $|\chi(R_j)| \geq |\chi(Q_j)|$.

If $R_1 \neq R_2$, then we have $|\chi(R_j)| = |\chi(Q_j)|$ for each $j = 1, 2$ because

$$|\chi(S)| = |\chi(R_1)| + |\chi(R_2)| \geq |\chi(Q_1)| + |\chi(Q_2)| = |\chi(S)|.$$

We assume $R_1 = R_2$ and denote it by R . For each $j = 1, 2$, pick a simplex σ_j of $\mathcal{C}_s(Q_j)$ of maximal dimension. The family $\tau = \{\phi_\alpha(\beta) \mid \beta \in \sigma_1 \cup \sigma_2\}$ is then a weakly rooted simplex of $\mathcal{T}(R)$ with

$$|\tau| = |\sigma_1| + |\sigma_2| = |\chi(Q_1)| + |\chi(Q_2)| - 2 = |\chi(S)| - 2.$$

On the other hand, since $\phi(\alpha)$ is neither an hp-curve in S nor a p-BP in S , we have $|\chi(R)| \leq |\chi(S)| - 2$. We thus have $|\tau| \leq |\chi(R)| - 1 \leq |\chi(S)| - 3$. This is a contradiction. $\square$

Proposition 5.7. *Let $S = S_{g,p}$ be a surface with $|\chi(S)| \geq 3$. Then any superinjective map $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ is χ -preserving.*

If $|\chi(S)| = 3$, then any separating curve in S is an hp-curve in S , and any BP in S is a p-BP in S . The proposition thus holds. The proposition for S with $|\chi(S)| \geq 4$ is obtained by combining Lemmas 5.8 and 5.9 below.

Lemma 5.8. *In the notation of Proposition 5.7, we assume $|\chi(S)| \geq 4$. Let α be a separating curve in S . If at least one component of S_α contains an even number of components of ∂S , then ϕ is χ -preserving at α .*

Proof. We first prove that if α is an hp-curve in S , then $\phi(\alpha)$ is either an hp-curve in S or a p-BP in S . Let σ be a simplex of $\mathcal{C}_s(S)$ of maximal dimension containing α . By Lemma 5.5, we have a component R of $S_{\phi(\alpha)}$ with $\phi_\alpha(\beta) \in V_t(R)$ for any $\beta \in \sigma \setminus \{\alpha\}$. The family $\{\phi_\alpha(\beta) \mid \beta \in \sigma \setminus \{\alpha\}\}$ is then a weakly rooted simplex of $\mathcal{T}(R)$ with its cardinality $|\sigma| - 1$. We thus have $|\chi(R)| - 1 \geq |\sigma| - 1 = |\chi(S)| - 2$, and $|\chi(R)| \geq |\chi(S)| - 1$. It turns out that $\phi(\alpha)$ is either an hp-curve in S or a p-BP in S .

We next assume that α is not an hp-curve in S . Since at least one component of S_α contains an even number of components of ∂S , there exists a simplex τ of $\mathcal{C}_s(S)$ consisting of α and $g + \lfloor p/2 \rfloor$ hp-curves in S . As shown in the previous paragraph, for any $\beta \in \tau \setminus \{\alpha\}$, $\phi(\beta)$ is either an hp-curve in S or a p-BP in S . By Lemma 5.3, $\phi(\alpha)$ is neither an hp-curve in S nor a p-BP in S . It follows from Lemma 5.6 that ϕ is χ -preserving at α . $\square$

FIGURE 5.

Lemma 5.9. *In the notation of Proposition 5.7, we assume $|\chi(S)| \geq 4$. Let α be a separating curve in S . If any component of S_α contains an odd number of components of ∂S , then ϕ is χ -preserving at α .*

Proof. By Lemma 5.6, either $\phi(\alpha)$ is an hp-curve in S ; $\phi(\alpha)$ is a p-BP in S ; or ϕ is χ -preserving at α . We eliminate the first two cases in Claims 5.10 and 5.11 below. Let σ be a simplex of $\mathcal{C}_s(S)$ of maximal dimension containing α and the two curves β_1, β_2 described in Figure 5 (a). For each $j = 1, 2$, choose $\gamma_j, \epsilon_j \in V_s(S)$ with

$$i(\gamma_j, \beta_j) \neq 0, \quad i(\gamma_j, \sigma \setminus \{\beta_j\}) = 0,$$

$$i(\epsilon_j, \alpha) \neq 0, \quad i(\epsilon_j, \beta_j) \neq 0, \quad i(\epsilon_j, \sigma \setminus \{\alpha, \beta_j\}) = 0.$$

In the proof of Claims 5.10 and 5.11 below, we use the following terminology and notation. Let v be a vertex of $\mathcal{T}(S)$. If $v \in V_s(S)$, then we mean by a *part* of v the element v itself. If $v \in V_{bp}(S)$, then we mean by a *part* of v an element of v . For each $\gamma \in V(S)$, if γ is a part of v , then we write $\gamma \in v$. Otherwise, we write $\gamma \notin v$.

Claim 5.10. *$\phi(\alpha)$ is not an hp-curve in S .*

Proof. Assuming that $\phi(\alpha)$ is an hp-curve in S , we deduce a contradiction. Let P denote the component of $S_{\phi(\sigma)}$ containing $\phi(\alpha)$ as its boundary component and distinct from the one cut off by $\phi(\alpha)$ from S . The component P is a pair of pants because otherwise P would be a handle by Lemma 5.1 (ii), and the equality $|\chi(S)| = 2$ would follow.

We show that no component of ∂P is a component of ∂S . If it were not true, then exactly one component of ∂P would be a component of ∂S . Let $\delta_0 \in V(S)$ denote the other component of ∂P distinct from $\phi(\alpha)$. The curve δ_0 is separating in S . If we had $\delta_0 \neq \phi(\beta_1)$, then $\phi(\epsilon_1)$ would be disjoint from δ_0 . This contradicts Lemma 2.1 because $\phi(\epsilon_1)$ intersects both $\phi(\alpha)$ and $\phi(\beta_1)$, which lie in distinct components of S_{δ_0} . We thus have $\delta_0 = \phi(\beta_1)$. We can however show the equality $\delta_0 = \phi(\beta_2)$ similarly. This is a contradiction.

Let $\delta_1, \delta_2 \in V(S)$ denote the curves in S corresponding to the two components of ∂P other than $\phi(\alpha)$ (see Figure 5 (b)). Since we assume $|\chi(S)| \geq 4$, we have $\delta_1 \neq \delta_2$. We put $\delta = \{\delta_1, \delta_2\}$. Note that S_δ consists of at least two components. Either δ is a BP in S or both δ_1 and δ_2 are separating curves in S . Let R denote the component of S_δ containing $\phi(\alpha)$. We set $R' = S_\delta \setminus R$. We aim to show that for each $j \bmod 2$, $\phi(\gamma_j)$ intersects δ_j and is disjoint from δ_{j+1} after exchanging indices if necessary. Once this is shown, $\phi(\gamma_1)$ and $\phi(\gamma_2)$ intersect in P because they are disjoint from $\phi(\alpha)$. This contradicts $i(\gamma_1, \gamma_2) = 0$.

We first assume that neither δ_1 nor δ_2 is a part of $\phi(\beta_1)$. Any part of $\phi(\beta_1)$ is then an essential curve in a component of R' . The assumption also implies that $\phi(\epsilon_1)$ is disjoint from δ . Since $\phi(\epsilon_1)$ intersects $\phi(\alpha)$ and $\phi(\beta_1)$, $\phi(\epsilon_1)$ is a BP in S with one curve of $\phi(\epsilon_1)$ essential in R and with another essential in a component of R' . By Lemma 2.1, $\phi(\epsilon_1)$ and δ are BPs in S and BP-equivalent. If $\delta \in \phi(\sigma)$, then we obtain a contradiction by Lemma 5.2. We suppose $\delta \notin \phi(\sigma)$. Let γ_3 and γ_4 be the elements of σ with $\delta_1 \in \phi(\gamma_3)$ and $\delta_2 \in \phi(\gamma_4)$. Each of γ_3 and γ_4 is distinct from α and β_1 . Since $\{\epsilon_1, \gamma_3, \gamma_4\}$ is a simplex of $\mathcal{C}_s(S)$, $\{\phi(\epsilon_1), \phi(\gamma_3), \phi(\gamma_4)\}$ is a weakly rooted simplex of $\mathcal{T}(S)$ by Lemma 5.2. Since the BPs $\phi(\epsilon_1)$, $\phi(\gamma_3)$ and $\phi(\gamma_4)$ are mutually BP-equivalent, they share a curve in S . This is a contradiction because each curve in $\phi(\epsilon_1)$ intersects either $\phi(\alpha)$ or $\phi(\beta_1)$, but each of $\phi(\gamma_3)$ and $\phi(\gamma_4)$ is disjoint from $\phi(\alpha)$ and $\phi(\beta_1)$. We thus proved that either $\delta_1 \in \phi(\beta_1)$ or $\delta_2 \in \phi(\beta_1)$ holds. Similarly, we can show that either $\delta_1 \in \phi(\beta_2)$ or $\delta_2 \in \phi(\beta_2)$ holds.

Let us assume $\delta_1 \in \phi(\beta_1)$. The following argument can be applied as well if we assume $\delta_2 \in \phi(\beta_1)$. Assuming $\delta_1 \in \phi(\beta_2)$, we first deduce a contradiction. The last assumption implies that $\phi(\beta_1)$ and $\phi(\beta_2)$ are BPs in S and that $\phi(\epsilon_1)$ is disjoint from δ_1 . Since $\phi(\sigma)$ is weakly rooted, δ_1 is the root curve for the BP-equivalence class in $\phi(\sigma)$ containing $\phi(\beta_1)$ and $\phi(\beta_2)$. We thus have $\delta \in \phi(\sigma)$. If we had $\delta_2 \notin \phi(\beta_1)$, then $\phi(\epsilon_1)$ would be disjoint from δ_2 , and $\phi(\beta_1)$ would consist of δ_1 and a curve in R' . Since $\phi(\epsilon_1)$ intersects $\phi(\beta_1)$, no part of $\phi(\epsilon_1)$ is an essential curve in R by Lemma 5.2. This is a contradiction because $\phi(\epsilon_1)$ intersects $\phi(\alpha)$. We thus have $\delta_2 \in \phi(\beta_1)$ and $\phi(\beta_1) = \{\delta_1, \delta_2\}$. However, $\phi(\epsilon_2)$ is then disjoint from δ_1 and δ_2 because we have $i(\epsilon_2, \beta_1) = 0$. The BP $\phi(\beta_2)$ consists of δ_1 and a curve in R' . Since $\phi(\epsilon_2)$ intersects $\phi(\beta_2)$, no part of $\phi(\epsilon_2)$ is an essential curve in R by Lemma 5.2. This is a contradiction because $\phi(\epsilon_2)$ intersects $\phi(\alpha)$. We have proved $\delta_1 \notin \phi(\beta_2)$ and thus $\delta_2 \in \phi(\beta_2)$.

Similarly, we can prove $\delta_2 \notin \phi(\beta_1)$ by using the condition $\delta_2 \in \phi(\beta_2)$. We now show that for each $j \bmod 2$, $\phi(\gamma_j)$ intersects δ_j and is disjoint from δ_{j+1} . This is true if both δ_1 and δ_2 are separating curves in S , for we then have $\delta_1 = \phi(\beta_1)$ and $\delta_2 = \phi(\beta_2)$. We assume that $\delta = \{\delta_1, \delta_2\}$ is a BP in S . It then follows that $\phi(\beta_1)$ and $\phi(\beta_2)$ are BPs in S and are BP-equivalent. The root curve for $\{\phi(\beta_1), \phi(\beta_2)\}$ is distinct from δ_1 and δ_2 because we have $\delta_1 \notin \phi(\beta_2)$ and $\delta_2 \notin \phi(\beta_1)$. It turns out that for each $j \bmod 2$, $\phi(\gamma_j)$ intersects δ_j and is disjoint from δ_{j+1} .

As indicated in the third paragraph of the proof, $\phi(\gamma_1)$ and $\phi(\gamma_2)$ intersects in P , and this contradicts $i(\gamma_1, \gamma_2) = 0$. $\square$

Claim 5.11. $\phi(\alpha)$ is not a p -BP in S .

Proof. Assuming that $\phi(\alpha)$ is a p -BP in S , we deduce a contradiction.

We first suppose that the set $\{\phi(\alpha)\}$ is a BP-equivalence class in $\phi(\sigma)$. Since any separating curve or BP in $\phi(\sigma) \setminus \{\phi(\alpha)\}$ cuts off a surface containing the two curves of $\phi(\alpha)$ from S , there exist exactly two components of $S_{\phi(\sigma)}$ homeomorphic to a pair of pants and containing the two curves in $\phi(\alpha)$ as their boundary components. Let P denote the one of them distinct from the one cut off by $\phi(\alpha)$ from S . Since we assume $|\chi(S)| \geq 4$, the component of ∂P distinct from the two curves in $\phi(\alpha)$ is not a component of ∂S . Let $\delta \in V(S)$ denote that component of ∂P (see Figure 6 (a)). The curve δ is separating in S . If $\delta \neq \phi(\beta_1)$, then $\phi(\epsilon_1)$ would be disjoint from δ . This contradicts Lemma 2.1 because $\phi(\epsilon_1)$ intersects both $\phi(\alpha)$ and $\phi(\beta_1)$, which lie in distinct components of S_δ . We thus have $\delta = \phi(\beta_1)$. We can however show the equality $\delta = \phi(\beta_2)$ similarly. This is a contradiction.

FIGURE 6.

We next suppose that the BP-equivalence class in $\phi(\sigma)$ containing $\phi(\alpha)$ consists of at least two BPs in S . Let α_0 denote the root curve for that class. We define a curve α_1 in S by the equality $\phi(\alpha) = \{\alpha_0, \alpha_1\}$. Let Q denote the component of $S_{\phi(\sigma)}$ containing α_1 as its boundary component and distinct from the pair of pants cut off by $\phi(\alpha)$ from S .

We show that no component of ∂Q is a component of ∂S . If it were not true, then exactly one component of ∂Q would be a component of ∂S . Let $\delta_0 \in V(S)$ denote the other component of ∂Q distinct from α_1 . Since $\{\delta_0, \alpha_1\}$ cuts off a pair of pants from S , the curve δ_0 is non-separating in S and BP-equivalent to α_1 . Since we assume $|\chi(S)| \geq 4$, we have $\delta_0 \neq \alpha_0$. The BP $\{\alpha_0, \delta_0\}$ thus belongs to $\phi(\sigma)$. Let R be the component of $S_{\{\alpha_0, \delta_0\}}$ containing α_1 , and put $R' = S_{\{\alpha_0, \delta_0\}} \setminus R$. If we had $\{\alpha_0, \delta_0\} \neq \phi(\beta_1)$, then $\phi(\epsilon_1)$ would be disjoint from $\{\alpha_0, \delta_0\}$, and any part of $\phi(\beta_1)$ would be either α_0 or an essential curve in R' . Since $\phi(\epsilon_1)$ intersects $\phi(\beta_1)$, no part of $\phi(\epsilon_1)$ is an essential curve in R by Lemma 5.2. This is a contradiction because $\phi(\epsilon_1)$ intersects α_1 . We thus have $\{\alpha_0, \delta_0\} = \phi(\beta_1)$. We can however show the equality $\{\alpha_0, \delta_0\} = \phi(\beta_2)$ similarly. This is a contradiction.

Let $\delta_1, \delta_2 \in V(S)$ denote the curves in S corresponding to the two components of ∂Q distinct from α_1 . The two curves δ_1 and δ_2 are distinct as elements of $V(S)$ because otherwise α_1 would be an h-curve in S .

If both δ_1 and δ_2 were separating in S , then α_1 would be separating in S . This is a contradiction. Without loss of generality, we may assume that δ_2 is non-separating in S . By Lemma 5.4, δ_1 is separating in S , and thus α_1 and δ_2 form a BP in S (see Figure 6 (b)). Note that $\delta_2 \neq \alpha_0$ because otherwise $\{\phi(\alpha)\}$ would be a BP-equivalence class in $\phi(\sigma)$. We thus have $\{\alpha_0, \delta_2\} \in \phi(\sigma)$.

Let T denote the component of $S_{\{\alpha_0, \delta_1, \delta_2\}}$ containing α_1 and put $T' = S_{\{\alpha_0, \delta_1, \delta_2\}} \setminus T$. If $\phi(\beta_1)$ were equal to neither δ_1 nor $\{\alpha_0, \delta_2\}$, then $\phi(\epsilon_1)$ would be disjoint from α_0, δ_1 and δ_2 , and any part of $\phi(\beta_1)$ would be either α_0 or an essential curve in a component of T' . Since $\phi(\epsilon_1)$ intersects $\phi(\beta_1)$, no part of $\phi(\epsilon_1)$ is an essential curve in T by Lemmas 2.1 and 5.2. This is a contradiction because $\phi(\epsilon_1)$ intersects α_1 . It follows that $\phi(\beta_1)$ is equal to either δ_1 or $\{\alpha_0, \delta_2\}$. Similarly, we can show that $\phi(\beta_2)$ is also equal to either δ_1 or $\{\alpha_0, \delta_2\}$.

Without loss of generality, we may put $\phi(\beta_1) = \delta_1$ and $\phi(\beta_2) = \{\alpha_0, \delta_2\}$. We then have

$$i(\phi(\gamma_1), \delta_1) \neq 0, \quad i(\phi(\gamma_2), \delta_2) \neq 0,$$

$$i(\phi(\gamma_1), \alpha_1) = i(\phi(\gamma_1), \delta_2) = i(\phi(\gamma_2), \alpha_1) = i(\phi(\gamma_2), \delta_1) = 0.$$

It follows that $\phi(\gamma_1)$ and $\phi(\gamma_2)$ intersect in Q . This contradicts $i(\gamma_1, \gamma_2) = 0$. $\square$

Claims 5.10 and 5.11 complete the proof of Lemma 5.9. $\square$

6. $S_{g,p}$ WITH $g \geq 3$ AND $p \leq 1$, AND $S_{2,2}$

Let $S = S_{g,p}$ be a surface, and let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. When $p = 0$, the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ is readily shown in Section 6.1. When $p \geq 1$, we prove the inclusion by induction on p throughout Sections 6–8. Sections 6.2–6.5 are devoted to the first step of the induction for surfaces of genus at least two. Namely, we deal with $S_{g,1}$ with $g \geq 3$ and $S_{2,2}$. In Section 7, the inclusion is proved for $S_{1,4}$, and this is the first step of the induction for surfaces of genus one. In Section 8, the induction is completed.

6.1. The case $p = 0$. If $S = S_{g,0}$ is a closed surface with $g \geq 3$, then there exists neither p-curve in S nor p-BP in S . This is why the proof of the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ for a closed surface is much easier than the other cases.

Proposition 6.1. *Let $S = S_{g,0}$ be a closed surface with $g \geq 3$, and let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. Then the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ holds.*

Proof. By Proposition 5.7, ϕ preserves h-curves in S . Let α be a separating curve in S which is not an h-curve in S . We can choose g h-curves $\beta_1, \dots, \beta_g$ in S forming a g -simplex of $\mathcal{C}_s(S)$ together with α . For each $j = 1, \dots, g$, $\phi(\beta_j)$ is an h-curve in S disjoint from $\phi(\alpha)$. It is thus impossible that $\phi(\alpha)$ is a BP in S . $\square$

6.2. The case $g \geq 3$ and $p = 1$. Let $S = S_{g,1}$ be a surface with $g \geq 3$, and let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. We fix an h-curve a in S and assume that $\phi(a)$ is a p-BP in S . We then deduce a contradiction throughout this subsection and Section 6.4. In Section 6.4, we deal with $S_{g,1}$ with $g \geq 3$ and $S_{2,2}$ together.

Lemma 6.2. *If z is a separating curve in S such that*

- $i(z, a) = 0$ and $z \neq a$; and
- *the component of S_z containing a does not contain ∂S ,*

then $\phi(z)$ is a BP in S which is BP-equivalent to $\phi(a)$.

Proof. Let Q be the component of S_z containing a . Let R be the component of $S_{\phi(z)}$ containing at least one curve of $\phi(a)$ as an essential one. We prove the lemma by induction on the genus of Q . The genus of Q is at least two because Q contains a as an essential curve.

Suppose that the genus of Q is equal to two. The surface Q is homeomorphic to $S_{2,1}$. By Proposition 5.7, we have $|\chi(R)| = |\chi(Q)| = 3$. Assuming that $\phi(z)$ is either a separating curve in S or a BP in S which is not BP-equivalent to $\phi(a)$, we deduce a contradiction. If $\phi(z)$ were a separating curve in S , then $|\chi(R)|$ would be even because the number of components of ∂R is equal to two. This is a contradiction. We next assume that $\phi(z)$ is a BP in S which is not BP-equivalent to $\phi(a)$. Let R' denote the component of $R_{\phi(a)}$ distinct from the pair of pants cut off by $\phi(a)$ from S . Since we have $|\chi(R')| = 2$, R' is homeomorphic to $S_{0,4}$, and $\partial R'$ consists of the four curves in $\phi(a) \cup \phi(z)$. Choose an h-curve b in Q disjoint and distinct from a . By Proposition 5.7, $\phi(b)$ is either an hp-curve in S or a p-BP in S . This

FIGURE 7. The double line is the root curve for $\{\phi(\alpha), \phi(\beta)\}$.

is impossible because $\phi(b)$ is disjoint from $\phi(a)$ and $\phi(z)$. It follows that $\phi(z)$ is a BP in S which is BP-equivalent to $\phi(a)$.

When the genus of Q , denoted by g_1 , is more than two, choose a separating curve z_1 in S such that

- $i(z_1, a) = i(z_1, z) = 0$, $z_1 \neq a$ and $z_1 \neq z$; and
- one component of S_{z_1} contains a and is homeomorphic to $S_{g_1-1,1}$, and another component contains z .

The hypothesis of the induction implies that $\phi(z_1)$ is a BP in S which is BP-equivalent to $\phi(a)$. Note that $\phi(a)$ and $\phi(z_1)$ share a curve by Lemma 5.2. The same argument as in the previous paragraph shows that $\phi(z)$ is a BP in S which is BP-equivalent to $\phi(z_1)$. The induction is completed. $\square$

Lemma 6.3. *If z is a separating curve in S such that*

- $i(z, a) = 0$ and $z \neq a$; and
- *the component of S_z containing a contains ∂S ,*

then $\phi(z)$ is a separating curve in S . Moreover, ϕ preserves the topological type of z . Namely, if we denote by Q_1 and Q_2 the two components of S_z , then for each $j = 1, 2$, Q_j and $\phi_z(Q_j)$ are homeomorphic, where we use the notation introduced right after the proof of Lemma 5.5.

Proof. We assume that $\phi(z)$ is a BP in S . The component of S_z , denoted by Q , that contains a has exactly two boundary component. We put $R = \phi_z(Q)$, which is the component of $S_{\phi(z)}$ containing at least one curve of $\phi(a)$ as an essential one. By our assumption, R has exactly three boundary components. It follows that Q and R cannot have the same Euler characteristic. This contradicts Proposition 5.7. We proved that $\phi(z)$ is a separating curve in S .

The latter assertion in the lemma follows because ϕ is χ -preserving and S has exactly one boundary component. $\square$

6.3. The case $g = 2$ and $p = 2$. This subsection is preliminary to Sections 6.4 and 6.5, where we prove the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ for $S = S_{g,1}$ with $g \geq 3$ and $S = S_{2,2}$ together.

Lemma 6.4. *Let $S = S_{2,2}$ be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Choose hp-curves α , β and γ in S which are mutually disjoint and distinct. We assume that at least one of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is a BP in S . Then the following assertions hold:*

- Exactly two of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ are BPs in S which are BP-equivalent, and another is an h-curve in S .*

FIGURE 8. (a) $S = S_{g,1}$ with $g \geq 3$; (b) $S = S_{2,2}$

(ii) If α is a p-curve in S , then $\phi(\alpha)$ is a BP in S (see Figure 7).

Proof. By Proposition 5.7, each of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is either an hp-curve in S or a p-BP in S . To prove assertion (i), let us assume that $\phi(\alpha)$ is a p-BP in S . It is impossible that both $\phi(\beta)$ and $\phi(\gamma)$ are hp-curves in S and that both $\phi(\beta)$ and $\phi(\gamma)$ are p-BPs in S . Exactly one of $\phi(\beta)$ and $\phi(\gamma)$ is thus a p-BP in S .

Let us assume that $\phi(\beta)$ is a p-BP in S . If $\phi(\alpha)$ and $\phi(\beta)$ were not BP-equivalent, then $\phi(\gamma)$ could not be an hp-curve in S because any vertex of $V_t(S)$ forming a 2-simplex of $\mathcal{T}(S)$ with $\phi(\alpha)$ and $\phi(\beta)$ corresponds to a separating curve in S which decomposes S into two surfaces homeomorphic to $S_{1,2}$. This is a contradiction. The BPs $\phi(\alpha)$ and $\phi(\beta)$ are thus BP-equivalent. It follows that $\phi(\gamma)$ is an h-curve in S . Assertion (i) is proved.

To prove assertion (ii), we next assume that α is a p-curve in S . If $\phi(\alpha)$ were not a p-BP in S , then assertion (i) would imply that $\phi(\alpha)$ is an h-curve in S and that both $\phi(\beta)$ and $\phi(\gamma)$ are p-BPs in S which are BP-equivalent. Choose a separating curve δ in S such that

- $i(\delta, \alpha) \neq 0$ and $i(\delta, \beta) = i(\delta, \gamma) = 0$; and
- both components of S_δ are homeomorphic to $S_{1,2}$.

Any vertex of $V_t(S)$ forming a 2-simplex of $\mathcal{T}(S)$ with $\phi(\beta)$ and $\phi(\gamma)$ corresponds to either the BP in S consisting of the curves in $\phi(\beta) \cup \phi(\gamma)$ distinct from the root curve for $\{\phi(\beta), \phi(\gamma)\}$ or an h-curve in S . It follows that $\phi(\delta)$ is an h-curve in S because $\phi(\delta)$ intersects $\phi(\alpha)$. This is a contradiction because ϕ is χ -preserving. $\square$

6.4. Construction of injective simplicial maps. Let $S = S_{g,p}$ be a surface with either $g \geq 3$ and $p = 1$ or $g = 2$ and $p = 2$. Let $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ be a superinjective map. Fix an h-curve a in S . The aim of this subsection is to deduce a contradiction on the assumption that $\phi(a)$ is a p-BP in S .

Let b, x, y, z and w denote the curves in S described in Figure 8. The choices of curves in (a) and (b) of Figure 8 are introduced in Figure 2 of [5] and Figure 10 of [14], respectively, to characterize sharing pairs in terms of disjointness and non-disjointness. We note that

- a and b are h-curves in S forming a sharing pair in S , and thus $i(a, b) \neq 0$;
- z cuts off a surface homeomorphic to $S_{2,1}$ and containing a and b ;
- x cuts off a surface homeomorphic to $S_{2,1}$ and containing b ;
- y is an h-curve in S ;

FIGURE 9. (a) $S = S_{g,1}$ with $g \geq 3$; (b) $S = S_{2,2}$

- w is an h-curve in S if $g \geq 3$, and is a p-curve in S if $S = S_{2,2}$;
- $i(w, a) = 0$, $i(w, b) = 0$ and $i(w, z) \neq 0$;
- $i(x, a) \neq 0$, $i(x, b) = 0$ and $i(x, z) \neq 0$;
- $i(y, a) = 0$, $i(y, b) \neq 0$ and $i(y, z) \neq 0$; and
- $i(x, y) = 0$.

Lemmas 6.2 and 6.3 imply that if $g \geq 3$, then

- $\phi(z)$ is a BP in S which is BP-equivalent to $\phi(a)$; and
- both $\phi(y)$ and $\phi(w)$ are h-curves in S .

Lemma 6.4 implies that if $S = S_{2,2}$, then

- $\phi(z)$ is a BP in S which is BP-equivalent to $\phi(a)$;
- $\phi(y)$ is an h-curve in S ; and
- $\phi(w)$ is a BP in S which is BP-equivalent to $\phi(a)$, and the three BPs $\phi(a)$, $\phi(z)$ and $\phi(w)$ share a non-separating curve in S .

The last property is verified as follows: If the three BPs $\phi(a)$, $\phi(z)$ and $\phi(w)$ did not share a non-separating curve in S , then the inclusion $\phi(a) \subset \phi(z) \cup \phi(w)$ would hold because $\{\phi(a), \phi(z)\}$ and $\{\phi(a), \phi(w)\}$ are rooted. This is a contradiction because $\phi(b)$ intersects $\phi(a)$, but is disjoint from $\phi(z)$ and $\phi(w)$.

We introduce several symbols employed in the rest of this subsection. Figure 9 will be helpful. Let c be the root curve for $\{\phi(a), \phi(z)\}$. We define two curves a_1 and z_1 in S by the equalities $\phi(a) = \{c, a_1\}$ and $\phi(z) = \{c, z_1\}$. We put $y_1 = \phi(y)$. We put $w_1 = \phi(w)$ if $g \geq 3$, and define a curve w_1 in S by the equality $\phi(w) = \{c, w_1\}$ if $S = S_{2,2}$. Let ∂ denote the component of ∂S contained in the pair of pants cut off by $\phi(a)$ from S . Let ∂_1 and ∂_2 denote the two boundary components of S_c corresponding to c , where ∂_1 is chosen so that a_1 cuts off a pair of pants containing ∂ and ∂_1 from S_c . Let Q denote the component of $S_{\phi(a) \cup \phi(z)}$ that contains neither ∂_1 nor ∂_2 . Let Y denote the component of $S_{\phi(z)}$ containing ∂ .

Fixing representatives of the isotopy classes of curves chosen above so that any two of them intersect minimally, we denote them by the same symbols as their isotopy classes. This ambiguity will be of no importance in the sequel.

Lemma 6.5. $\phi(b)$ is not an h-curve in S .

Proof. Assume that $\phi(b)$ is an h-curve in S . The curve $\phi(b)$ is an h-curve in Y because $\phi(b)$ is disjoint from $\phi(z)$. Note that w_1 intersects z_1 and is disjoint from

a_1 and $\phi(b)$. The intersection $w_1 \cap Y$ consists of essential simple arcs in Y because w_1 and z_1 intersect minimally. Since $\phi(b)$ is an h-curve in Y , any component of $w_1 \cap Y$ is separating in Y . Since we have $w_1 \cap Y = w_1 \cap Q$, any component of $w_1 \cap Q$ is separating in Q . This is impossible because $\phi(b)$ is an h-curve in Y disjoint from w_1 and z_1 , but intersecting a_1 . $\square$

Lemma 6.6. *$\phi(b)$ is a p-BP in S containing c .*

Proof. When $g \geq 3$, Lemma 6.5 implies that $\phi(b)$ is a p-BP in S because there is no p-curve in S . By Lemma 6.2, $\phi(b)$ and $\phi(z)$ are BP-equivalent. When $S = S_{2,2}$, Lemmas 6.4 and 6.5 imply that $\phi(b)$ is a p-BP in S which is BP-equivalent to $\phi(z)$. It follows that in both cases, $\{\phi(b), \phi(z)\}$ is rooted. If the three BPs $\phi(a)$, $\phi(b)$ and $\phi(z)$ did not share a non-separating curve in S , then we would have the inclusion $\phi(z) \subset \phi(a) \cup \phi(b)$. This is a contradiction because $\phi(w)$ is disjoint from $\phi(a)$ and $\phi(b)$, but intersects $\phi(z)$. $\square$

We define a curve b_1 in S by the equality $\phi(b) = \{c, b_1\}$.

Lemma 6.7. *$\phi(x)$ is a BP in S which is BP-equivalent to $\phi(b)$ and contains c .*

Proof. Since $\phi(b)$ is a p-BP in S disjoint from $\phi(x)$, Lemmas 6.2 and 6.4 imply that $\phi(x)$ is a BP in S which is BP-equivalent to $\phi(b)$. By Lemma 5.2, $\{\phi(b), \phi(x)\}$ is rooted. If c were not contained in $\phi(x)$, then b_1 would be contained in $\phi(x)$. The inclusion $\phi(b) \subset \phi(a) \cup \phi(x)$ thus holds. This is a contradiction because $\phi(y)$ is disjoint from $\phi(a)$ and $\phi(x)$, but intersects $\phi(b)$. $\square$

We define a curve x_1 in S by the equality $\phi(x) = \{c, x_1\}$.

Lemma 6.8. *The two p-curves a_1, b_1 in Y form a sharing pair in Y . Namely, there exist essential simple arcs l_a, l_b in Y satisfying the following conditions:*

- each of l_a and l_b connects ∂ and ∂_1 ;
- l_a is disjoint from a_1 ; l_b is disjoint from b_1 ;
- l_a and l_b are disjoint and non-isotopic; and
- the surface obtained by cutting Y along $l_a \cup l_b$ is connected.

Proof. The following argument is inspired by the proof of Lemma 4.1 of [4].

Claim 6.9. *The intersection $w_1 \cap Q$ consists of mutually isotopic, essential simple arcs in Q which are non-separating in Q .*

Proof. Each component of $b_1 \cap Q$ is an essential simple arc in Q which is non-separating in Q . For if there were a component of $b_1 \cap Q$ which is separating in Q , then there would be no room for $w_1 \cap Q$ because w_1 is disjoint from a_1 and b_1 . Cutting Q along a component of $b_1 \cap Q$, we obtain a pair of pants. The claim follows because each component of $w_1 \cap Q$ is an essential simple arc in this pair of pants. $\square$

Let l_w be a component of $w_1 \cap Q$.

Claim 6.10. *Each component of $y_1 \cap Y$ is an essential simple arc in Y which is non-separating in Y . At least one component of $y_1 \cap Y$ is not isotopic to l_w .*

Proof. We first assume that there were a component l of $y_1 \cap Y$ which is separating in Y . The arc l is disjoint from a_1 and is thus an essential simple arc in Q which is separating in Q . Since x_1 is disjoint from y_1 and intersects a_1 , there exists a

component of $x_1 \cap Y$ cutting off an annulus from Y . The annulus contains exactly one of ∂ and ∂_1 . This contradicts the existence of the p-curve b_1 in Y cutting off ∂ and ∂_1 and disjoint from x_1 . It follows that each component of $y_1 \cap Y$ is non-separating in Y .

If any component of $y_1 \cap Y$ were isotopic to l_w , then b_1 would be disjoint from y_1 because b_1 is disjoint from w_1 . This contradicts $i(\phi(b), \phi(y)) \neq 0$. $\square$

The following claim is verified by a verbatim argument after exchanging a_1 and y_1 with b_1 and x_1 , respectively.

Claim 6.11. *Each component of $x_1 \cap Y$ is an essential simple arc in Y which is non-separating in Y . At least one component of $x_1 \cap Y$ is not isotopic to l_w .*

We choose a component of $y_1 \cap Y$ non-isotopic to l_w , denoted by l_y . Similarly, we choose a component of $x_1 \cap Y$ non-isotopic to l_w , denoted by l_x . Let R denote the surface obtained by cutting Y along l_w . The surface R is homeomorphic to $S_{0,4}$ and contains ∂ and ∂_1 . We denote by ∂_3 and ∂_4 the two boundary components of R distinct from ∂ and ∂_1 .

Let us say that two essential simple arcs l_1, l_2 in Y *intersect minimally* if the cardinality of $l_1 \cap l_2$ is equal to the minimal cardinality of $r_1 \cap r_2$ among essential simple arcs r_1 and r_2 in Y isotopic to l_1 and l_2 , respectively. Choose essential simple arcs r_x, r_y in Y such that

- r_x is isotopic to l_x ; r_y is isotopic to l_y ; and
- any two of r_x, r_y and l_w intersect minimally.

We can find a curve $\bar{b}_1$ in Y isotopic to b_1 and disjoint from r_x and l_w . Similarly, we can find a curve $\bar{a}_1$ in Y isotopic to a_1 and disjoint from r_y and l_w . Since l_x and l_y are disjoint, r_x and r_y are disjoint. When we cut Y along l_w and obtain R , the arc r_y is decomposed into finitely many, essential simple arcs in R each of which connects two distinct points of $\partial_3 \cup \partial_4$. Let L_y be the set of those essential simple arcs in R . In the same manner, we define the set L_x after replacing r_y with r_x .

We claim that each arc in L_y connects ∂_3 and ∂_4 and that all arcs in L_y are mutually isotopic as essential simple arcs in R . If there were an arc s in L_y connecting two points of ∂_3 , then s would be separating in R and cut off a pair of pants containing ∂ and ∂_1 from R because s is disjoint from the curve $\bar{a}_1$ in R cutting off a pair of pants containing ∂ and ∂_1 from R . Let u be an arc in L_x . Since r_x and r_y are disjoint, either u cuts off an annulus containing exactly one of ∂ and ∂_1 from R ; u is isotopic to s ; or u connects ∂_3 and ∂_4 . The first case is impossible because r_x is disjoint from the curve $\bar{b}_1$ in R cutting off a pair of pants containing ∂ and ∂_1 from R . In the second and third cases, $\bar{a}_1$ and $\bar{b}_1$ has to be isotopic because $\bar{b}_1$ is disjoint from u . This is a contradiction. A verbatim argument shows that L_y contains no arc connecting two points of ∂_4 . Any arc in L_y thus connects ∂_3 and ∂_4 . Since r_y is disjoint from $\bar{a}_1$, all arcs in L_y are mutually isotopic.

Similarly, we can show that any arc in L_x connects ∂_3 and ∂_4 , and all arcs in L_x are mutually isotopic. Pick $s_y \in L_y$ and $s_x \in L_x$. The curve a_1 is isotopic to a boundary component of a regular neighborhood of $s_y \cup \partial_3 \cup \partial_4$ in R . Similarly, b_1 is isotopic to a boundary component of a regular neighborhood of $s_x \cup \partial_3 \cup \partial_4$ in R . The two arcs s_y and s_x are disjoint and non-isotopic because a_1 and b_1 are non-isotopic. We can therefore find essential simple arcs l_a, l_b in R satisfying the conditions in Lemma 6.8. $\square$

FIGURE 10. (a) $S = S_{g,1}$ with $g \geq 3$; (b) $S = S_{2,2}$

We define b' and w' as the two curves in S described in Figure 10. The argument so far can also be applied to the family of curves, a , b' , x , y , z and w' , in place of a , b , x , y , z and w . In particular, the following assertions hold:

- $\phi(b')$ is a p-BP in S containing c . We define a curve b'_1 in S by the equality $\phi(b') = \{c, b'_1\}$. The curve b'_1 is a p-curve in Y cutting off ∂ and ∂_1 .
- Since each of $\{a, b'\}$ and $\{b, b'\}$ is a sharing pair in S , there exists an essential simple arc $l_{b'}$ in Y satisfying the following three conditions: $l_{b'}$ is disjoint from b'_1 and connects ∂ and ∂_1 ; l_a , l_b and $l_{b'}$ are mutually disjoint and non-isotopic; and the surface obtained by cutting Y along any two of l_a , l_b and $l_{b'}$ is connected.
- $\phi(w')$ is an h-curve in S if $g \geq 3$, and is a p-BP in S containing c if $S = S_{2,2}$. We put $w'_1 = \phi(w')$ if $g \geq 3$, and define a curve w'_1 in S by the equality $\phi(w') = \{c, w'_1\}$ if $S = S_{2,2}$.
- The intersection $w'_1 \cap Q$ consists of mutually isotopic, essential simple arcs in Q which are non-separating in Q . Let $l_{w'}$ be a component of $w'_1 \cap Q$.

Lemma 6.12. *There exist essential simple arcs $r_w, r_{w'}$ in Q such that r_w is isotopic to l_w ; $r_{w'}$ is isotopic to $l_{w'}$; r_w and $r_{w'}$ are disjoint and non-isotopic; and the end points of r_w and $r_{w'}$ appear alternately along the component of ∂Q corresponding to z_1 .*

Proof. We define T_1 as the surface obtained by cutting Y along l_a . Let ∂_0 denote the boundary component of T_1 consisting of four arcs corresponding to ∂ , ∂_1 and two copies of l_a . The arcs l_b and $l_{b'}$ are essential simple arcs in T_1 connecting two points of ∂_0 and non-separating in T_1 .

We claim that the end points of l_b and $l_{b'}$ appear alternately along ∂_0 . Let T_2 denote the surface obtained by cutting T_1 along l_b , which is a pair of pants. We have two components of ∂T_2 each of which consists of four arcs corresponding to ∂ , ∂_1 , l_a and l_b (see Figure 11 (a)). If the claim were not true, then up to a homeomorphism of Y fixing each of ∂ , ∂_1 , l_a and l_b as a set, we would have the two possibilities for $l_{b'}$ indicated in Figure 11 (b) and (c). In case (b), the surface obtained by cutting Y along $l_a \cup l_{b'}$ is not connected. In case (c), the surface obtained by cutting Y along $l_b \cup l_{b'}$ is not connected. We thus obtain a contradiction in both cases.

The claim shown in the last paragraph and Remark 4.6 imply that l_b and $l_{b'}$ are described as in Figure 11 (d) up to a homeomorphism of T_1 . Since T_2 is a pair of pants, the arc l_w is uniquely determined, up to isotopy, as an essential simple arc in T_1 which is disjoint from l_b and connects two points of the boundary component of

FIGURE 11.

T_1 corresponding to z_1 . Similarly, up to isotopy, $l_{w'}$ is uniquely determined by $l_{b'}$. We can thus find essential simple arcs $r_w, r_{w'}$ in T_1 isotopic to $l_w, l_{w'}$, respectively, and described as in Figure 11 (d). The lemma is proved. $\square$

Let X denote the component of S_z containing a , which is homeomorphic to $S_{2,1}$. We note that each of $w \cap X$ and $w' \cap X$ consists of two isotopic, essential simple arcs in X which are non-separating in X . We can find essential simple arcs $s_w, s_{w'}$ in X such that s_w is isotopic to a component of $w \cap X$; $s_{w'}$ is isotopic to a component of $w' \cap X$; s_w and $s_{w'}$ are disjoint and non-isotopic; and the end points of s_w and $s_{w'}$ appear alternately along the component of ∂X corresponding to z . Let $\mathcal{B} = \mathcal{B}(X, a; s_w, s_{w'})$ be the simplicial graph defined in Section 4.4. Recall that the set of vertices of $\mathcal{B}$ is the union $B(s_w) \cup B(s_{w'})$. The set $B(s_w)$ consists of all elements β of $V(X)$ such that β is an h-curve in X ; a and β form a sharing pair in X ; and a representative of β is disjoint from s_w . The last condition is equivalent to the condition that β is disjoint from w as a curve in S . The set $B(s_{w'})$ is defined similarly after exchanging s_w with $s_{w'}$.

Let $\mathcal{G} = \mathcal{G}(Y, a_1; r_w, r_{w'})$ be the simplicial graph defined in Section 4.3. The set of vertices of $\mathcal{G}$ is the union $\Gamma(r_w) \cup \Gamma(r_{w'})$. The set $\Gamma(r_w)$ consists of all elements γ of $V(Y)$ such that γ is a p-curve in Y cutting off ∂ and ∂_1 ; a_1 and γ form a sharing pair in Y ; and a representative of γ and r_w are disjoint. The last condition is equivalent to the condition that γ is disjoint from w_1 as a curve in S by Claim 6.9. The set $\Gamma(r_{w'})$ is defined similarly after exchanging r_w with $r_{w'}$.

We are now ready to deduce a contradiction on the assumption that $\phi(a)$ is a p-BP in S . Since for each $\beta \in B(s_w)$, $\phi(\beta)$ is a p-BP in S consisting of c and an element of $\Gamma(r_w)$ by Lemmas 6.6 and 6.8, we have the map from $B(s_w)$ to $\Gamma(r_w)$

FIGURE 12.

associated with ϕ . Similarly, we have the map from $B(s_{w'})$ to $\Gamma(r_{w'})$ associated with ϕ . By Lemma 6.8, ϕ induces a simplicial map from $\mathcal{B}$ to $\mathcal{G}$, which is injective because ϕ is injective. This contradicts Lemma 4.12. We thus proved the following:

Lemma 6.13. *If a is an h-curve in S , then $\phi(a)$ is not a p-BP in S .*

6.5. Conclusion. We first conclude the following:

Theorem 6.14. *Let $S = S_{g,1}$ be a surface with $g \geq 3$ and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Then the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ holds.*

Proof. Lemma 6.13 implies that ϕ sends each h-curve in S to an h-curve in S because there is no p-curve in S . Let α be a separating curve in S which is not an hp-curve in S . Choose g h-curves in S forming a g -simplex of $\mathcal{C}_s(S)$ together with α . The map ϕ sends each of those g h-curves in S to an h-curve in S . It follows that $\phi(\alpha)$ is not a BP in S . $\square$

We next conclude the following:

Theorem 6.15. *Let $S = S_{2,2}$ be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Then the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ holds.*

Proof. Lemmas 6.4 and 6.13 imply that ϕ preserves hp-curves in S . Once ϕ is shown to preserve h-curves in S , the theorem is verified along argument in the proof of Theorem 6.14. Assuming that there exists an h-curve a in S with $\phi(a)$ a p-curve in S , we deduce a contradiction. The proof consists of verbatim arguments of the proof of Lemma 6.13. We thus give only a sketch of it.

We choose the curves b, x, y, z and w in S described in Figure 8 (b). Since ϕ preserves hp-curves in S and since $\phi(a)$ is a p-curve in S , each of $\phi(y)$, $\phi(z)$ and $\phi(w)$ is an h-curve in S . We denote by ∂_1 and ∂_2 the two components of ∂S . Let Q denote the component of $S_{\{\phi(a), \phi(z)\}}$ homeomorphic to $S_{1,2}$. Let Y denote the component of $S_{\phi(z)}$ that is not a handle (see Figure 12).

Following the proof of Lemma 6.5, we can show that $\phi(b)$ is not an h-curve in S and is thus a p-curve in S . It turns out that $\phi(x)$ is an h-curve in S because $\phi(x)$ is an hp-curve in S disjoint from $\phi(b)$. Following the proof of Lemma 6.8, we can show that

- $\phi(a)$ and $\phi(b)$ form a sharing pair in Y ; and

- $\phi(w) \cap Q$ consists of mutually isotopic, essential simple arcs in Q which are non-separating in Q .

Choose the curves b', w' in S described in Figure 10 (b). We can then show that

- $\phi(b')$ is a p-curve in Y cutting off ∂_1 and ∂_2 ;
- any two of $\phi(a)$, $\phi(b)$ and $\phi(b')$ form a sharing pair in Y ;
- $\phi(w')$ is an h-curve in S ; and
- $\phi(w') \cap Q$ consists of mutually isotopic, essential simple arcs in Q which are non-separating in Q .

Following the proof of Lemma 6.12, we can find essential simple arcs $r_w, r_{w'}$ in Q such that r_w is isotopic to a component of $\phi(w) \cap Q$; $r_{w'}$ is isotopic to a component of $\phi(w') \cap Q$; r_w and $r_{w'}$ are disjoint and non-isotopic; and the end points of r_w and $r_{w'}$ appear alternately along the component of ∂Q corresponding to $\phi(z)$. Let $\mathcal{G} = \mathcal{G}(Y, \phi(a); r_w, r_{w'})$ be the graph defined in Section 4.3.

Let X denote the component of S_z containing a , which is homeomorphic to $S_{2,1}$. As discussed in the paragraph right after the proof of Lemma 6.12, we pick essential simple arcs $s_w, s_{w'}$ in X and define the graph $\mathcal{B} = \mathcal{B}(X, a; s_w, s_{w'})$. We then obtain the injective simplicial map from $\mathcal{B}$ into $\mathcal{G}$ associated with ϕ . This contradicts Lemma 4.12. $\square$

7. $S_{1,4}$

We start with the following brief observation on hp-curves in $S_{1,4}$ and their image via a superinjective map into the Torelli complex.

Lemma 7.1. *Let $S = S_{1,4}$ be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Choose hp-curves α, β and γ in S which are mutually disjoint and distinct. We assume that at least one of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is a BP in S . Then exactly one of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is a p-curve in S , and the others are p-BPs in S .*

Proof. By our assumption, each of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is either a p-curve in S or a p-BP in S . Suppose that $\phi(\alpha)$ is a p-BP in S . Since it is impossible that both $\phi(\beta)$ and $\phi(\gamma)$ are p-curves in S , one of them, say $\phi(\beta)$, is a p-BP in S . If $\phi(\gamma)$ were also a p-BP in S , then $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ would be mutually BP-equivalent because S is of genus one. This contradicts the fact that each BP-equivalence class in a weakly rooted simplex of $\mathcal{T}(S)$ contains at most two p-BPs in S . $\square$

Let α, β and γ be hp-curves in S which are mutually disjoint and distinct. Throughout Sections 7.1 and 7.2, we deduce a contradiction on the assumption that at least one of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is a BP in S . We may assume that α is an h-curve in S and both β and γ are p-curves in S . In Section 7.1, assuming that $\phi(\alpha)$ is a p-curve in S , we deduce a contradiction. In Section 7.2, assuming that $\phi(\beta)$ is a p-curve in S , we deduce a contradiction. Once these are proved, we see that each of $\phi(\alpha)$, $\phi(\beta)$ and $\phi(\gamma)$ is an hp-curve in S by Lemma 7.1. In Section 7.3, we conclude that ϕ preserves separating curves in S .

Throughout the rest of this section, we put $S = S_{1,4}$ and fix a superinjective map $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$.

7.1. The case where $\phi(\alpha)$ is a p-curve in S . Let α be an h-curve in S and β, γ p-curves in S such that $\{\alpha, \beta, \gamma\}$ is a 2-simplex of $\mathcal{C}_s(S)$. Assuming that $\phi(\alpha)$ is a p-curve in S and that both $\phi(\beta)$ and $\phi(\gamma)$ are p-BPs in S , we deduce a contradiction. Let Q denote the component of $S_{\{\beta, \gamma\}}$ homeomorphic to $S_{1,2}$. We denote by ∂_1 and

FIGURE 13. The double line is the root curve for $\{\phi(\beta), \phi(\gamma)\}$.

∂_2 the two components of ∂S that are not contained in the pairs of pants cut off by $\phi(\beta)$ and $\phi(\gamma)$ from S . We define R to be the component of $S_{\{\phi(\beta), \phi(\gamma)\}}$ containing ∂_1 and ∂_2 . Let β_1 and γ_1 denote the curves of $\phi(\beta)$ and $\phi(\gamma)$, respectively, distinct from the root curve for $\{\phi(\beta), \phi(\gamma)\}$ (see Figure 13).

Lemma 7.2. *In the above notation, the following assertions hold:*

- (i) *For each h -curve a in Q , $\phi(a)$ is a curve in R cutting off a pair of pants containing ∂_1 and ∂_2 from R .*
- (ii) *If α_1 and α_2 are h -curves in Q with $i(\alpha_1, \alpha_2) = 4$, then $i(\phi(\alpha_1), \phi(\alpha_2)) = 4$.*

Proof. Assertion (i) follows from Lemma 7.1. To prove assertion (ii), we choose the p -curves δ_1, δ_2 in S described in Figure 14. We then have

$$i(\delta_1, \alpha_2) = i(\delta_2, \alpha_1) = i(\delta_1, \delta_2) = 0,$$

$$i(\delta_j, \alpha_j) \neq 0, \quad i(\delta_j, \beta) \neq 0, \quad i(\delta_j, \gamma) \neq 0 \quad \text{for any } j = 1, 2.$$

Let l be an essential simple arc in R connecting two points of $\beta_1 \cup \gamma_1$. We note that up to isotopy, there exists exactly one curve in R disjoint from l . If the curve in R cuts off a pair of pants containing ∂_1 and ∂_2 from R , then either

- (1) l is a separating arc in R connecting two points of β_1 and cutting off from R an annulus containing γ_1 as its boundary component;
- (2) l is a separating arc in R connecting two points of γ_1 and cutting off from R an annulus containing β_1 as its boundary component; or
- (3) l is an arc connecting a point of β_1 with a point of γ_1 .

We denote by P the component of $R_{\phi(\alpha_1)}$ containing β_1 and γ_1 as its boundary components. Since P is a pair of pants, the intersection $\phi(\alpha_2) \cap P$ consists of mutually isotopic, essential simple arcs in P connecting two points of the component of ∂P corresponding to $\phi(\alpha_1)$. It follows that $\phi(\delta_2)$ intersects $\phi(\alpha_2) \cap P$ because $\phi(\delta_2)$ is disjoint from $\phi(\alpha_1)$ and intersects $\phi(\alpha_2)$. The intersection $\phi(\delta_2) \cap R$ is thus non-empty and contains an essential simple arc in R , denoted by l_2 , connecting two points of $\beta_1 \cup \gamma_1$. Similarly, the same property holds for $\phi(\delta_1) \cap R$. We pick an essential simple arc in R contained in $\phi(\delta_1) \cap R$ and denote it by l_1 . The existence of $\phi(\alpha_1)$ and $\phi(\alpha_2)$ implies that each of l_1 and l_2 satisfies one of conditions (1), (2) and (3). We note that if an essential simple arc r_1 in R satisfying one of (1), (2) and (3) is disjoint from an essential simple arc r_2 in R satisfying either (1) or (2), then the curve in R disjoint from r_1 and the curve in R disjoint from r_2 are isotopic. It follows that if there were $j \in \{1, 2\}$ such that l_j satisfies either (1) or (2), then we would have the equality $\phi(\alpha_1) = \phi(\alpha_2)$. This is a contradiction. Each of l_1 and l_2 therefore connects a point of β_1 with a point of γ_1 . Since $\phi(\delta_1)$ and $\phi(\delta_2)$ are

FIGURE 14.

disjoint, so are l_1 and l_2 . Since $\phi(\alpha_1)$ and $\phi(\alpha_2)$ intersect, l_1 and l_2 are not isotopic. By Proposition 4.1, we have $i(\phi(\alpha_1), \phi(\alpha_2)) = 4$. Assertion (ii) follows. $\square$

We define $\mathcal{D} = \mathcal{D}(Q)$ and $\mathcal{E} = \mathcal{E}(R; \partial_1, \partial_2)$ to be the simplicial graphs introduced in Sections 4.2 and 4.1, respectively. It follows from Lemma 7.2 that ϕ induces an injective simplicial map from $\mathcal{D}$ into $\mathcal{E}$. This contradicts Lemma 4.10. We therefore obtain the following:

Lemma 7.3. *Let $S = S_{1,4}$ be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Choose an h-curve α in S and p-curves β, γ in S such that $\{\alpha, \beta, \gamma\}$ is a 2-simplex of $\mathcal{C}_s(S)$. Then it is impossible that $\phi(\alpha)$ is a p-curve in S and each of $\phi(\beta)$ and $\phi(\gamma)$ is a p-BP in S .*

7.2. The case where $\phi(\beta)$ is a p-curve in S . We fix two disjoint and distinct p-curves β, γ in S . Throughout this subsection, we deduce a contradiction on the assumption that $\phi(\beta)$ is a p-curve in S and that $\phi(\gamma)$ is a p-BP in S . By Lemma 7.1, ϕ sends each h-curve in S disjoint from β and γ to a p-BP in S containing a curve of $\phi(\gamma)$. Let us introduce symbols employed in this subsection.

Let γ_1 and γ_2 denote the two curves of $\phi(\gamma)$. We denote by Q the component of $S_{\{\beta, \gamma\}}$ homeomorphic to $S_{1,2}$ and denote by R the component of $S_{\{\phi(\beta), \phi(\gamma)\}}$ homeomorphic to $S_{0,4}$. Let ∂ denote the component of ∂S contained in R (see Figure 15). For each h-curve α in S disjoint from β and γ , we define $c(\alpha) \in V(R)$ to be the curve of the p-BP $\phi(\alpha)$ that is not contained in $\phi(\gamma)$. We define $\mathcal{F}$ as the simplicial graph $\mathcal{F}(R)$ introduced in Section 4.1.

Lemma 7.4. *In the above notation, the following assertions hold:*

- (i) *For each h-curve α in Q , the two components of ∂R corresponding to γ_1 and γ_2 are contained in distinct components of $R_{c(\alpha)}$.*
- (ii) *If α_1 and α_2 are h-curves in Q with $i(\alpha_1, \alpha_2) = 4$, then either we have $i(c(\alpha_1), c(\alpha_2)) = 2$ or $c(\alpha_1)$ and $c(\alpha_2)$ lie in a diagonal position of two adjacent triangles in $\mathcal{F}$.*

Proof. Assertion (i) follows because for each h-curve α in Q , the curve $c(\alpha)$ is non-separating in S . We prove assertion (ii). Pick two h-curves α_1, α_2 in Q with $i(\alpha_1, \alpha_2) = 4$. As in the proof of Lemma 7.2, we choose the p-curves δ_1, δ_2 in S described in Figure 14. We then have

$$i(\delta_1, \alpha_2) = i(\delta_2, \alpha_1) = i(\delta_1, \delta_2) = 0,$$

$$i(\delta_j, \alpha_j) \neq 0, \quad i(\delta_j, \beta) \neq 0, \quad i(\delta_j, \gamma) \neq 0 \quad \text{for any } j = 1, 2.$$

FIGURE 15.

For each $j = 1, 2$, we choose a component l_j of $\phi(\delta_j) \cap R$ at least one of whose end points lies in $\phi(\beta)$. The arc l_j is simple and essential in R . We list several properties of l_1 and l_2 below.

- Each l_j connects a point of $\phi(\beta)$ with a point of $\phi(\beta) \cup \gamma_1 \cup \gamma_2$. For each $j \bmod 2$, up to isotopy, $c(\alpha_j)$ is a unique curve in R disjoint from l_{j+1} .
- The arcs l_1 and l_2 are not isotopic because otherwise $c(\alpha_1)$ and $c(\alpha_2)$ would be isotopic, and this would contradict $i(\phi(\alpha_1), \phi(\alpha_2)) \neq 0$.
- The arcs l_1 and l_2 are disjoint because $\phi(\delta_1)$ and $\phi(\delta_2)$ are disjoint.
- For each $j \bmod 2$, if both end points of l_j lie in $\phi(\beta)$, then l_j cuts off an annulus containing exactly one of γ_1 and γ_2 . For otherwise l_j would cut off an annulus containing ∂ , and $c(\alpha_{j+1})$ would be separating in S .

For each $j = 1, 2$, if l_j connects a point of $\phi(\beta)$ with a point of $\gamma_1 \cup \gamma_2$, then we set $r_j = l_j$. If l_j connects two points of $\phi(\beta)$, then we define r_j to be an essential simple arc in R disjoint from l_j and connecting a point of $\phi(\beta)$ with a point of the component of $\gamma_1 \cup \gamma_2$ contained in the annulus cut off by l_j from R . This arc is uniquely determined up to isotopy.

Let us say that two essential simple arcs s_1 and s_2 in R are *disjoint* if s_1 and s_2 can be isotoped so that they are disjoint. For each essential simple arc s in R , if s is disjoint from l_j , then s is disjoint from r_j . It follows that r_1 and r_2 are disjoint.

If the end points of r_1 and r_2 that are not in $\phi(\beta)$ lie in distinct components of $\gamma_1 \cup \gamma_2$, then the equality $i(c(\alpha_1), c(\alpha_2)) = 2$ follows. If all of those points lie in γ_k for some $k \in \{1, 2\}$, then $c(\alpha_1)$ and $c(\alpha_2)$ lie in a diagonal position of two adjacent triangles in $\mathcal{F}$ by Proposition 4.1. Assertion (ii) is proved. $\square$

We now deduce a contradiction. Let $\mathcal{D} = \mathcal{D}(Q)$ be the graph defined in Section 4.2. Let $\mathcal{H} = \mathcal{H}(R; \gamma_1, \gamma_2)$ be the graph defined in Section 4.1. If α_1 and α_2 are distinct h-curves in Q , then we have $i(\alpha_1, \alpha_2) \neq 0$ and thus $i(\phi(\alpha_1), \phi(\alpha_2)) \neq 0$. Since each of $\phi(\alpha_1)$ and $\phi(\alpha_2)$ is a p-BP in S containing a curve in $\phi(\gamma)$, we have $i(c(\alpha_1), c(\alpha_2)) \neq 0$. In particular, we have $c(\alpha_1) \neq c(\alpha_2)$. The map c from the set of h-curves in Q into the set of curves in R is therefore injective and induces a simplicial map from $\mathcal{D}$ into $\mathcal{H}$ by Lemma 7.4. This contradicts Lemma 4.11. We thus obtain the following:

Lemma 7.5. *Let $S = S_{1,4}$ be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Choose an h-curve α in S and p-curves β, γ in S such that $\{\alpha, \beta, \gamma\}$ is a 2-simplex*

of $\mathcal{C}_s(S)$. Then it is impossible that $\phi(\beta)$ is a p-curve in S and each of $\phi(\alpha)$ and $\phi(\gamma)$ is a p-BP in S .

7.3. Conclusion. We conclude the following:

Theorem 7.6. *Let $S = S_{1,4}$ be a surface and $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ a superinjective map. Then the inclusion $\phi(\mathcal{C}_s(S)) \subset \mathcal{C}_s(S)$ holds.*

Proof. As discussed in the beginning of this section, Lemmas 7.1, 7.3 and 7.5 imply that ϕ preserves hp-curve in S . Once ϕ is shown to preserve h-curves in S , it turns out that for any separating curve a in S that is not an hp-curve in S , $\phi(a)$ is not a BP in S . For there exists an h-curve b in S disjoint from a , and $\phi(a)$ is disjoint from the h-curve $\phi(b)$ in S . The theorem thus follows.

Assuming that there exists an h-curve α in S with $\phi(\alpha)$ a p-curve in S , we deduce a contradiction. Choose p-curves β, γ in S such that $\{\alpha, \beta, \gamma\}$ is a 2-simplex of $\mathcal{C}_s(S)$. We note that one of $\phi(\beta)$ and $\phi(\gamma)$ is an h-curve in S and another is a p-curve in S . Let Q denote the component of $S_{\{\beta, \gamma\}}$ homeomorphic to $S_{1,2}$. Let R denote the component of $S_{\{\phi(\beta), \phi(\gamma)\}}$ homeomorphic to $S_{0,4}$. We denote by ∂_1 and ∂_2 the two components of ∂S contained in R . For each h-curve a in Q , $\phi(a)$ is a curve in R cutting off a pair of pants containing ∂_1 and ∂_2 from R .

In the proof of Lemma 7.2 (ii), after replacing β_1 and γ_1 with $\phi(\beta)$ and $\phi(\gamma)$, respectively, a verbatim argument shows that for any two h-curves α_1, α_2 in Q with $i(\alpha_1, \alpha_2) = 4$, we have $i(\phi(\alpha_1), \phi(\alpha_2)) = 4$. It follows that ϕ induces an injective simplicial map from the graph $\mathcal{D}(Q)$ into the graph $\mathcal{E}(R; \partial_1, \partial_2)$. These two graphs are defined in Sections 4.2 and 4.1, respectively. Since such an injective simplicial map does not exist by Lemma 4.10, we obtain a contradiction. $\square$

8. THE OTHER SURFACES

In this section, we discuss the remainder of surfaces. Let S be a surface and pick two distinct components ∂_1, ∂_2 of ∂S . For each vertex a of $\mathcal{T}(S)$, we say that a separates ∂_1 and ∂_2 if ∂_1 and ∂_2 are contained in distinct components of S_a .

Theorem 8.1. *Let $S = S_{g,p}$ be a surface and assume one of the following three conditions: $g \geq 3$ and $p \geq 1$; $g = 2$ and $p \geq 2$; or $g = 1$ and $p \geq 4$. If $\phi: \mathcal{C}_s(S) \rightarrow \mathcal{T}(S)$ is a superinjective map, then ϕ is induced by an element of $\text{Mod}^*(S)$.*

Proof. We prove the theorem by induction on p . In the case where S is either $S_{g,1}$ with $g \geq 3$, $S_{2,2}$ or $S_{1,4}$, the conclusion follows from Theorems 2.2, 6.14, 6.15 and 7.6. In what follows, we assume that S is distinct from these surfaces.

Lemma 8.2. *The map ϕ sends each p-curve in S to an hp-curve in S .*

Proof. Assuming that there is a p-curve α in S with $\phi(\alpha)$ a p-BP in S , we deduce a contradiction. Let Q denote the component of S_α that is not a pair of pants. Let ∂ denote the component of ∂S cut off by $\phi(\alpha)$. We define R as the surface obtained from S by attaching a disk to ∂ . Let $\mathcal{C}^*(R)$ be the simplicial cone over $\mathcal{C}(R)$ with $*$ the cone point. We define $\iota: \mathcal{C}(S) \rightarrow \mathcal{C}^*(R)$ as the simplicial map associated with the inclusion of S into R , where $\iota^{-1}(\{*\})$ consists of all p-curves in S cutting off ∂ . The map ι sends the two curves in $\phi(\alpha)$ to the same non-separating curve in R , denoted by c .

We define a superinjective map $\phi_\alpha: \mathcal{C}_s(Q) \rightarrow \mathcal{T}(R)$ as follows. Pick a separating curve β in S disjoint and distinct from α . If $\phi(\beta)$ is a separating curve in S , then

FIGURE 16.

$\iota(\phi(\beta))$ is a separating curve in R , and we set $\phi_\alpha(\beta) = \iota(\phi(\beta))$. If $\phi(\beta)$ is a BP in S containing no curve in $\phi(\alpha)$, then $\phi(\beta)$ is not BP-equivalent to $\phi(\alpha)$ by Lemma 5.2, and thus $\iota(\phi(\beta))$ is a BP in R . We set $\phi_\alpha(\beta) = \iota(\phi(\beta))$. If $\phi(\beta)$ is a BP in S containing a curve in $\phi(\alpha)$, then we denote by β_1 another curve in $\phi(\beta)$. The pair $\{c, \iota(\beta_1)\}$ is a BP in R , and we set $\phi_\alpha(\beta) = \{c, \iota(\beta_1)\}$. The map $\phi_\alpha: V_s(Q) \rightarrow V_t(R)$ then defines a superinjective map from $\mathcal{C}_s(Q)$ into $\mathcal{T}(R)$.

Since both Q and R are homeomorphic to $S_{g,p-1}$, the hypothesis of the induction implies that ϕ_α is induced by a homeomorphism from Q onto R . For any $\gamma \in V_s(Q)$, $\phi_\alpha(\gamma)$ is however disjoint from c . This is a contradiction. $\square$

Lemma 8.3. *The map ϕ sends each hp-curve in S to an hp-curve in S .*

Proof. Let α be an h-curve in S . By Lemma 8.2, it is enough to show that $\phi(\alpha)$ is an hp-curve in S . Choose the p-curve β in S and the separating curves β', γ in S described in Figure 16 (a).

We first suppose that $\phi(\beta)$ is a p-curve in S . Let Q_1 denote the component of S_β that is not a pair of pants. Let Q_2 denote the component of $S_{\phi(\beta)}$ that is not a pair of pants. The map ϕ induces a superinjective map from $\mathcal{C}_s(Q_1)$ into $\mathcal{T}(Q_2)$. The hypothesis of the induction then implies that $\phi(\alpha)$ is an h-curve in S .

We next suppose that $\phi(\beta)$ is not a p-curve in S and is thus an h-curve in S by Lemma 8.2. If $\phi(\alpha)$ were a p-BP in S , then $\phi(\gamma)$ would be a BP in S and BP-equivalent to $\phi(\alpha)$ because ϕ is χ -preserving (see Figure 16 (b)). We deduce a contradiction by proving that there is no room for $\phi(\beta')$. Let R be the component of $S_{\phi(\alpha) \cup \phi(\gamma)}$ containing $\phi(\beta)$. If $\phi(\beta')$ is a separating curve in S , then $\phi(\beta')$ has to be an h-curve in S because $\phi(\beta')$ lies in R . This is a contradiction because ϕ is χ -preserving. If $\phi(\beta')$ is a BP in S and BP-equivalent to $\phi(\alpha)$, then $\{\phi(\alpha), \phi(\beta'), \phi(\gamma)\}$ is rooted by Lemma 5.2. This is a contradiction because any separating curve in R is an h-curve in S . If $\phi(\beta')$ is a BP in S and not BP-equivalent to $\phi(\alpha)$, then $\phi(\beta')$ is a BP in R . This is a contradiction because no BP in R is a BP in S . $\square$

We first prove the theorem when $g \geq 3$ and $p = 2$, which is a direct consequence of Theorem 2.2 and the following:

Lemma 8.4. *If we have $S = S_{g,2}$ with $g \geq 3$, then ϕ sends each separating curve in S to a separating curve in S .*

Proof. Once we prove that ϕ sends each h-curve in S to an h-curve in S , we can deduce the lemma along argument in the proof of Theorem 6.14. Assume that there exists an h-curve α in S with $\phi(\alpha)$ a p-curve in S . We choose a g -simplex σ of $\mathcal{C}_s(S)$

consisting of hp-curves in S and containing α . Since $\phi(\sigma)$ also consists of hp-curves in S , if β denotes the p-curve in σ , then $\phi(\beta)$ is an h-curve in S . Let Q denote the component of S_β that is not a pair of pants. Let R denote the component of $S_{\phi(\beta)}$ that is not a handle.

We claim that for each separating curve γ in Q which is not an h-curve in Q , $\phi(\gamma)$ is not a BP in S . Choose a $(g-1)$ -simplex τ of $\mathcal{C}_s(Q)$ consisting of h-curves in Q and disjoint from γ . By Lemma 8.3, $\phi(\tau)$ consists of $g-1$ h-curves in R and one p-curve in R . It turns out that $\phi(\gamma)$ is not a BP in S because $\phi(\gamma)$ is disjoint from the $g-1$ h-curves in $\phi(\tau)$ and the h-curve $\phi(\beta)$ in S . The claim is proved.

The claim shown in the last paragraph implies that ϕ induces a superinjective map $\phi_\beta: \mathcal{C}_s(Q) \rightarrow \mathcal{C}_s(R)$. Let ∂_1 denote the component of ∂R corresponding to $\phi(\beta)$. Let ∂_2 denote another component of ∂R , which is a component of ∂S . Gluing ∂_1 with ∂_2 , we obtain the surface, denoted by R_1 , homeomorphic to $S_{g,1}$. Let c denote the non-separating curve in R_1 corresponding to ∂_1 and ∂_2 . We denote by $\iota: \mathcal{C}(R) \rightarrow \mathcal{C}(R_1)$ the simplicial map associated with the inclusion of R onto the complement of a tubular neighborhood of c in R_1 .

We define a superinjective map $\bar{\iota}: \mathcal{C}_s(R) \rightarrow \mathcal{T}(R_1)$ as follows. Pick a separating curve δ in R . If δ separates ∂_1 and ∂_2 , then we define $\bar{\iota}(\delta)$ to be the BP $\{c, \iota(\delta)\}$ in R_1 . Otherwise, $\iota(\delta)$ is a separating curve in R_1 , and we set $\bar{\iota}(\delta) = \iota(\delta)$. The map $\bar{\iota}: V_s(R) \rightarrow V_t(R_1)$ then defines a superinjective map from $\mathcal{C}_s(R)$ into $\mathcal{T}(R_1)$.

Let $\phi_1: \mathcal{C}_s(Q) \rightarrow \mathcal{T}(R_1)$ be the superinjective map defined as the composition $\bar{\iota} \circ \phi_\beta$. Since both Q and R_1 are homeomorphic to $S_{g,1}$, we have the inclusion $\phi_1(\mathcal{C}_s(Q)) \subset \mathcal{C}_s(R_1)$ by Theorem 6.14. On the other hand, by the definition of ϕ_1 , we have $\phi_1(\alpha) = \{c, \iota(\phi(\alpha))\}$, which is a BP in R_1 . This is a contradiction. $\square$

Finally, we assume either $g \geq 2$ and $p \geq 3$ or $g = 1$ and $p \geq 5$. Let us say that a separating curve α in S is *even* if at least one component of S_α contains an even number of components of ∂S . Otherwise, α is said to be *odd*. We note that if there exists an odd separating curve in S , then p is even.

Lemma 8.5. *If α is an even separating curve in S , then $\phi(\alpha)$ is a separating curve in S .*

Proof. By Lemma 8.3, we may assume that α is not an hp-curve in S . Since α is even, there exist $g + \lfloor p/2 \rfloor$ hp-curves in S forming a $(g + \lfloor p/2 \rfloor)$ -simplex of $\mathcal{C}_s(S)$ together with α . Since the image of those hp-curves via ϕ contains g h-curves in S by Lemma 8.3, $\phi(\alpha)$ is not a BP in S . $\square$

Lemma 8.6. *We assume that p is even and $p \geq 4$. If α is an odd separating curve in S , then $\phi(\alpha)$ is a separating curve in S .*

Proof. Assume that there exists an odd separating curve α in S with $\phi(\alpha)$ a BP in S . We first prove the following:

Claim 8.7. *If β is an odd separating curve in S disjoint and distinct from α , then $\phi(\beta)$ is a BP in S and BP-equivalent to $\phi(\alpha)$.*

Proof. Let β be an odd separating curve in S disjoint and distinct from α . We choose even separating curves $\alpha_1, \beta_1, \gamma$ and γ_1 in S as described in Figure 17 (a). There then exists a simplex σ of $\mathcal{C}_s(S)$ of maximal dimension such that

- σ contains $\alpha, \alpha_1, \beta, \beta_1$ and γ ; and
- any curve of σ other than α and β is even.

FIGURE 17.

By Lemma 8.5, any element of $\phi(\sigma) \setminus \{\phi(\alpha), \phi(\beta)\}$ is a separating curve in S . Each component of $S_{\phi(\sigma)}$ is either a handle or a pair of pants by Lemma 5.1 (ii). Note that $\phi(\alpha)$ is not a p-BP in S because α is not an hp-curve in S .

Assuming that $\phi(\beta)$ is a separating curve in S , we deduce a contradiction. Since any element of $\phi(\sigma)$ other than $\phi(\alpha)$ is then a separating curve in S , there exist exactly two components of $S_{\phi(\sigma)}$ each of whose boundary components contains both curves of $\phi(\alpha)$ (see Figure 17 (b)). The number of curves δ of $\phi(\sigma) \setminus \{\phi(\alpha)\}$ satisfying the following condition is thus equal to two: There exists a vertex $\epsilon \in V_t(S)$ with $i(\phi(\alpha), \epsilon) \neq 0$, $i(\delta, \epsilon) \neq 0$ and $i(\delta', \epsilon) = 0$ for any $\delta' \in \phi(\sigma) \setminus \{\phi(\alpha), \delta\}$. On the other hand, each of $\phi(\alpha_1)$, $\phi(\beta)$ and $\phi(\gamma)$ satisfies this condition because for each of α_1 , β and γ , there exists a component of S_σ containing it and α as boundary components. This is a contradiction. It turns out that $\phi(\beta)$ is a BP in S .

If $\phi(\beta)$ were not BP-equivalent to $\phi(\alpha)$, then there would exist a separating curve δ in $\phi(\sigma)$ such that $\phi(\alpha)$ and $\phi(\beta)$ are contained in distinct components of S_δ . On the other hand, the hp-curve $\phi(\gamma_1)$ intersects $\phi(\alpha)$ and $\phi(\beta)$ and is disjoint from the other elements of $\phi(\sigma)$. This is impossible. $\square$

We return to the proof of Lemma 8.6. Choose a component of S_α containing at least three components of ∂S and denote it by R . If R is homeomorphic to $S_{0,4}$, then pick an odd separating curve α_1 in S cutting off a surface, denoted by R_1 , containing R and homeomorphic to $S_{1,4}$. If R is not homeomorphic to $S_{0,4}$, then we put $\alpha_1 = \alpha$ and $R_1 = R$. We can then choose separating curves α_2, α_3 in R_1 as described in Figure 17 (c). The curves α_1 and α_3 are odd, and α_2 is even. By Claim 8.7, $\phi(\alpha_1)$ is a BP in S . Applying Claim 8.7 to α_1 in place of α , we see that $\phi(\alpha_3)$ is also a BP in S and BP-equivalent to $\phi(\alpha_1)$. By Lemma 8.5, $\phi(\alpha_2)$ is a separating curve in S . The two BPs $\phi(\alpha_1)$ and $\phi(\alpha_3)$ are contained in the same component of $S_{\phi(\alpha_2)}$ by Lemma 2.1, while α_1 and α_3 are contained in distinct components of S_{α_2} . This contradicts Proposition 5.7. $\square$

We proved that ϕ preserves separating curves in S . By Theorem 2.2, ϕ is induced by an element of $\text{Mod}^*(S)$. The proof of Theorem 8.1 is completed. $\square$

9. PROOF OF THEOREMS 1.4 AND 1.5

Proof of Theorem 1.4. Let $S = S_{g,p}$ be a surface with $g \geq 1$ and $|\chi(S)| \geq 4$. We put $G = \text{Mod}^*(S)$ and pick a subgroup Γ of $\text{Mod}^*(S)$ with $[\mathcal{K}(S) : \Gamma \cap \mathcal{K}(S)] < \infty$ and $[\Gamma : \Gamma \cap \mathcal{I}(S)] < \infty$. Note that Γ contains a finite index subgroup of $\mathcal{K}(S)$ and

that there exists a finite index subgroup of Γ contained in $\mathcal{I}(S)$. Let

$$\mathbf{i}: \text{Comm}_G(\Gamma) \rightarrow \text{Comm}(\Gamma)$$

be the natural homomorphism. If γ is an element of $\text{Comm}_G(\Gamma)$ with $\mathbf{i}(\gamma)$ neutral, then there exists a finite index subgroup of Γ such that any element in it commutes γ . It follows that for any $a \in V_s(S)$, there exists a non-zero integer n with $\gamma t_a^n \gamma^{-1} = t_a^n$, and thus we have $\gamma a = a$. For each non-separating curve b in S , we can find two separating curves a_1, a_2 in S such that they are disjoint from b and fill S_b . Since γ fixes a_1 and a_2 , it also fixes b . The element γ thus fixes any element of $V(S)$ and is neutral. Injectivity of $\mathbf{i}$ follows.

To prove surjectivity of $\mathbf{i}$, we may assume that Γ is contained in $\mathcal{I}(S)$. Let Γ_1 and Γ_2 be finite index subgroups of Γ , and let $f: \Gamma_1 \rightarrow \Gamma_2$ be an isomorphism. Since $\Gamma_1 \cap \mathcal{K}(S)$ is a finite index subgroup of $\mathcal{K}(S)$, there exists an element γ_0 of G with the equality $f(\gamma) = \gamma_0 \gamma \gamma_0^{-1}$ for any $\gamma \in \Gamma_1 \cap \mathcal{K}(S)$ by Theorem 1.3.

We claim that the equality $f(\gamma) = \gamma_0 \gamma \gamma_0^{-1}$ holds for any $\gamma \in \Gamma_1$. This implies surjectivity of $\mathbf{i}$. Pick $\gamma \in \Gamma_1$. For any $a \in V_s(S)$, we have

$$\begin{aligned} f(\langle t_{\gamma a} \rangle \cap \Gamma_1) &= f(\gamma \langle t_a \rangle \cap \Gamma_1 \gamma^{-1}) < f(\gamma) \langle \gamma_0 t_a \gamma_0^{-1} \rangle \cap \Gamma_2 f(\gamma)^{-1} \\ &= \langle t_{f(\gamma) \gamma_0 a} \rangle \cap \Gamma_2, \end{aligned}$$

where for each $x \in G$, $\langle x \rangle$ denotes the group generated by x . We thus have $\gamma_0 \gamma a = f(\gamma) \gamma_0 a$. It follows that $\gamma^{-1} \gamma_0^{-1} f(\gamma) \gamma_0$ fixes any element of $V_s(S)$. The argument in the end of the first paragraph of the proof shows that $\gamma^{-1} \gamma_0^{-1} f(\gamma) \gamma_0$ is neutral. $\square$

To prove Theorem 1.5, we need the following two lemmas.

Lemma 9.1. *Let N be a group with a finite chain of subgroups, $\{e\} = N_0 < N_1 < \dots < N_m = N$, such that for each $j = 1, \dots, m$,*

- N_{j-1} is a normal subgroup of N_j ; and
- N_j/N_{j-1} is finitely generated and abelian.

Let H be a subgroup of N . If f is an automorphism of N with $f(H) < H$ and $f(N_j) = N_j$ for each $j = 0, 1, \dots, m$, then we have $f(H) = H$.

Proof. We put $H_j = H \cap N_j$ for $j = 0, 1, \dots, m$. We prove the equality $f(H_j) = H_j$ by induction on j . When $j = 0$, it is obvious. We assume $j \geq 1$. Put $M = N_j/N_{j-1}$ and let ϕ denote the automorphism of M induced by f . Let K denote the subgroup H_j/H_{j-1} of M . Since M is abelian, K is a normal subgroup of M . By assumption, we have $\phi(K) < K$. It follows that ϕ induces a surjective homomorphism from M/K onto itself, which is injective because M/K is finitely generated and abelian. The equality $\phi(K) = K$ thus holds. On the other hand, by the hypothesis of the induction, the equality $f(H_{j-1}) = H_{j-1}$ holds. We therefore obtain the equality $f(H_j) = H_j$. $\square$

Lemma 9.2. *Let $S = S_{1,p}$ be a surface with $p \geq 1$. Then there exists a chain of normal subgroups of $\text{PMod}(S)$,*

$$\mathcal{K}(S) = N_0 < N_1 < \dots < N_{p-2} < N_{p-1} = \mathcal{I}(S),$$

such that N_j/N_{j-1} is finitely generated and abelian for any $j = 1, \dots, p-1$.

Proof. We prove the lemma by induction on p . If $p = 1$, then $\mathcal{I}(S)$ is trivial, and the lemma follows. Assume $p \geq 2$. Pick a boundary component ∂ of S , and let $\bar{S}$ denote the surface obtained by attaching a disk to ∂ . Let

$$1 \rightarrow \pi_1(\bar{S}) \xrightarrow{\iota} \text{PMod}(S) \xrightarrow{\theta} \text{PMod}(\bar{S}) \rightarrow 1$$

be the associated Birman exact sequence (see Chapter 4 in [3]). We then have

$$\theta(\mathcal{I}(S)) = \mathcal{I}(\bar{S}), \quad \theta(\mathcal{K}(S)) = \mathcal{K}(\bar{S}), \quad \iota(\pi_1(\bar{S})) < \mathcal{I}(S).$$

We define H as the subgroup of $\mathcal{I}(S)$ generated by $\mathcal{K}(S)$ and $\iota(\pi_1(\bar{S}))$, which is a normal subgroup of $\text{PMod}(S)$. By the hypothesis of the induction, there exists a chain of normal subgroups of $\text{PMod}(\bar{S})$,

$$\mathcal{K}(\bar{S}) = \bar{N}_0 < \bar{N}_1 < \cdots < \bar{N}_{p-2} = \mathcal{I}(\bar{S}),$$

such that $\bar{N}_j/\bar{N}_{j-1}$ is finitely generated and abelian for any $j = 1, \dots, p-2$. Setting $N_j = \theta^{-1}(\bar{N}_{j-1})$ for each $j = 1, \dots, p-1$, we obtain the chain of normal subgroups of $\text{PMod}(S)$,

$$H = N_1 < N_2 < \cdots < N_{p-1} = \mathcal{I}(S)$$

with N_j/N_{j-1} isomorphic to $\bar{N}_{j-1}/\bar{N}_{j-2}$ for each $j = 2, \dots, p-1$.

We claim that $H/\mathcal{K}(S)$ is finitely generated and abelian. This claim completes the induction. Since we have a homomorphism from $\pi_1(\bar{S})$ onto $H/\mathcal{K}(S)$, the group $H/\mathcal{K}(S)$ is finitely generated. Choose generators $a, b, c_1, \dots, c_{p-1}$ of $\pi_1(\bar{S})$ such that each of them is a simple loop in $\bar{S}$; any two of them intersect only at the base point; a and b are non-separating in $\bar{S}$; and each c_j surrounds a single component of $\partial\bar{S}$. By the definition of ι , any $\iota(c_j)$ belongs to $\mathcal{K}(S)$ because $\iota(c_j)$ is the Dehn twist about a p -curve in S . The commutator $[a, b]$ represents a separating simple loop cutting off a handle from $\bar{S}$. By the definition of ι , $\iota([a, b])$ is written as $t_\alpha t_\beta^{-1}$ for some distinct elements α, β of $V_s(S)$ with $i(\alpha, \beta) = 0$. It follows that $\iota([a, b])$ belongs to $\mathcal{K}(S)$. The group $H/\mathcal{K}(S)$ is therefore abelian. $\square$

Proof of Theorem 1.5. Let $S = S_{g,p}$ be a surface with either $g \geq 3$ and $p \leq 1$ or $g = 1$ and $p \geq 4$. Let Γ be a subgroup of $\text{Mod}^*(S)$ with $[\mathcal{K}(S) : \Gamma \cap \mathcal{K}(S)] < \infty$ and $[\Gamma : \Gamma \cap \mathcal{I}(S)] < \infty$. Let $f : \Gamma \rightarrow \Gamma$ be an injective homomorphism. We put $\Gamma' = f^{-1}(\Gamma \cap \mathcal{I}(S)) \cap \mathcal{K}(S)$, which is a finite index subgroup of $\mathcal{K}(S)$. Applying Theorem 1.3 to the restriction of f to Γ' , we obtain an element γ of $\text{Mod}^*(S)$ with the equality $f(x) = \gamma x \gamma^{-1}$ for any $x \in \Gamma'$. As in the final paragraph of the proof of Theorem 1.4, we can show that this equality also holds for any $x \in \Gamma$. The inclusion $\gamma \Gamma \gamma^{-1} < \Gamma$ thus holds. We have to show that the equality indeed holds.

For any positive interger n , we have $\gamma^n \Gamma \gamma^{-n} < \gamma^{n-1} \Gamma \gamma^{-n+1} < \Gamma$. It follows that if there exists a positive integer n with $\gamma^n \Gamma \gamma^{-n} = \Gamma$, then the desired equality is obtained. We may therefore assume that γ is an element of $\text{PMod}(S)$.

We set

$$\Gamma_0 = \Gamma \cap \mathcal{K}(S), \quad \Gamma_1 = \Gamma \cap \mathcal{I}(S), \quad \mathcal{Q} = \text{PMod}(S)/\mathcal{K}(S)$$

and define $\iota : \text{PMod}(S) \rightarrow \mathcal{Q}$ as the canonical quotient map. For each $j = 0, 1$, the inclusion $\gamma \Gamma_j \gamma^{-1} < \Gamma_j$ then holds. Since we have

$$[\mathcal{K}(S) : \gamma \Gamma_0 \gamma^{-1}] = [\gamma \mathcal{K}(S) \gamma^{-1} : \gamma \Gamma_0 \gamma^{-1}] = [\mathcal{K}(S) : \Gamma_0] < \infty,$$

we obtain $[\Gamma_0 : \gamma \Gamma_0 \gamma^{-1}] = 1$ and thus $\gamma \Gamma_0 \gamma^{-1} = \Gamma_0$.

We now assume $g \geq 3$ and $p \leq 1$. It is known that $\iota(\mathcal{I}(S)) = \mathcal{I}(S)/\mathcal{K}(S)$ is a finitely generated and abelian group, due to Johnson (see Theorems 5 and 6 in [13]).

Since the conjugation by $\iota(\gamma)$ induces an automorphism of $\iota(\mathcal{I}(S))$, the inclusion $\iota(\gamma)\iota(\Gamma_1)\iota(\gamma)^{-1} < \iota(\Gamma_1)$ implies the equality $\iota(\gamma)\iota(\Gamma_1)\iota(\gamma)^{-1} = \iota(\Gamma_1)$. Combining the equality $\gamma\Gamma_0\gamma^{-1} = \Gamma_0$, we obtain $\gamma\Gamma_1\gamma^{-1} = \Gamma_1$. Since we have

$$[\Gamma : \Gamma_1] = [\gamma\Gamma\gamma^{-1} : \gamma\Gamma_1\gamma^{-1}] = [\gamma\Gamma\gamma^{-1} : \Gamma_1] < \infty,$$

we obtain $[\Gamma : \gamma\Gamma\gamma^{-1}] = 1$ and thus $\gamma\Gamma\gamma^{-1} = \Gamma$.

We next assume $g = 1$ and $p \geq 4$. By Lemma 9.2, we have a chain of normal subgroups of $\text{PMod}(S)$,

$$\mathcal{K}(S) = N_0 < N_1 < \cdots < N_{p-2} < N_{p-1} = \mathcal{I}(S),$$

such that N_j/N_{j-1} is finitely generated and abelian for any $j = 1, \dots, p-1$. By applying Lemma 9.1 to the chain of normal subgroups of $\mathcal{Q}$,

$$\{e\} = \iota(N_0) < \iota(N_1) < \cdots < \iota(N_{p-2}) < \iota(N_{p-1}) = \iota(\mathcal{I}(S)),$$

and to the inclusion $\iota(\gamma)\iota(\Gamma_1)\iota(\gamma)^{-1} < \iota(\Gamma_1)$, we obtain $\iota(\gamma)\iota(\Gamma_1)\iota(\gamma)^{-1} = \iota(\Gamma_1)$. Following argument in the previous paragraph, we obtain $\gamma\Gamma\gamma^{-1} = \Gamma$. $\square$
